SUBAPPENDIX H-4
OPERABLE UNIT MONITORING WELLS SOIL PHYSICAL ANALYTICAL RESULTS

This page left intentionally blank.

TABLE H-4. SUMMARY OF SOIL PHYSICAL RESULTS FOR MONITORING WELLS

Monitoring Well	Sample Id	Sample Depth (ft)	Sample Date	Moisture Content (%)	Unified Soil Classification (Group Criteria Only)
MW-1	1	10.5 - 12.1	01/11/90	1.26	Gravel with fines
MW-1	2	21.0 - 22.0	01/13/90	3.80	Gravel
MW-1	3	29.3 - 31.3	01/13/90	2.73	Gravel with fines
MW-1	4	34.0 - 35.0	01/13/90	1.77	Gravel
MW-1	5	40.0 - 41.7	01/15/90	4.19	Sand
MW-1	6	44.3 - 46.3	01/15/90	**	Gravel
MW-1	7	47.0 - 48.0	01/15/90	**	Gravel
MW-1	8	55.2 - 56.8	01/16/90	**	Gravel
MW-1	9	92.0 - 94.0	01/22/90	**	Fine-Grained Soil
MW-2	1	11.5 - 12.8	01/25/90	2.18	Gravel with fines
MW-2	2	19.0 - 20.0	01/25/90	1.76	Gravel with fines
MW-2	3	26.0 - 27.0	01/26/90	**	Sand with fines
MW-3	A2403	2.5 - 4.1	02/07/90	5.43	Sand with fines
MW-3	A2406	7.4 - 8.8	02/07/90	2.59	Gravel with fines
MW-3	A2408	15.1 - 16.9	02/08/90	2.48	Gravel with fines
MW-3	A2410	23.2 - 24.8	02/08/90	2.72	Sand with fines
MW-3	A2412	35.3 - 37.0	02/09/90	3.57	Gravel with fines
MW-3	A2414	36.6 - 39.2	02/09/90	4.21	Gravel with fines
MW-3	1	64.7 - 67.0	02/14/90	**	Gravel with fines
MW-3	2	74.0 - 76.3	02/15/90	**	Gravel
MW-3	3	81.7 - 83.7	02/16/90	**	Sand with fines
MW-4	1	8.5 - 9.5	11/09/89	2.00	Sand with fines
MW-4	2	16.0 - 17.0	11/10/89	3.00	Sand with fines
MW-4	3	31.0 - 32.0	11/13/89	2.16	Gravel
MW-4	4	50.0 - 52.0	11/15/89	**	Sand with fines
MW-4	5	56.0 - 58.0	11/16/89	**	Sand
MW-4	7	60.0 - 62.0	11/17/90	**	Sand
MW-5	1	2.4 - 2.5	12/07/89	2.41	Sand with fines
MW-5	2	5.8 - 6.0	12/07/89	2.41	Sand with fines
MW-5	3	14.5 - 15.0	12/07/89	**	Sand with fines
MW-5	4	18.5 - 19.0	12/08/89	2.11	Sand
MW-5	5	34.5 - 35.0	12/11/89	1.47	Gravel
MW-5	6	48.0 - 48.5	12/12/89	4.56	Gravel with fines
MW-5	7	50.0 - 50.5	12/12/89	**	Gravel
MW-5	8	54.5 - 55.0	12/13/89	**	Sand with fines
MW-5	9	64.5 - 66.5	12/14/89	**	Gravel
MW-5	10	69.7 - 70.7	12/15/89	**	Gravel
MW-5	11	74.5 - 76.5	12/15/89	**	Gravel
MW-5	12	79.5 - 81.5	12/18/89	**	Gravel
MW-5	13	86.6 - 88.6	12/18/89	**	Fine-Grained Soil
MW-6	1	24.0 - 25.0	11/13/89	2.08	Sand with fines
MW-6	2	43.0 - 44.4	11/13/89	4.16	Gravel

TABLE H-4. SUMMARY OF SOIL PHYSICAL RESULTS FOR MONITORING WELLS (CONT'D.)

Monitoring Well	Sample Id	Sample Depth (ft)	Sample Date	Moisture Content (%)	Unified Soil Classification (Group Criteria Only)
MW-6	3	49.4 - 51.4	11/15/89	**	-
MW-6	4	85.0 - 87.0	11/20/89	**	Sand with fines

APPENDIX I
SOIL CHEMICAL ANALYTICAL RESULTS

Surface and subsurface soil chemical analyses were completed by Weyerhaeuser Analytical and Testing Services. The Westinghouse Hanford Office of Sample Management provided the validated data summarized in this appendix. A complete set of data is available in the DOE-RL 1100-EM-1 Administrative Record. The DOE-RL 1100-EM-1 Administrative Record is managed by Westinghouse Hanford's Department of Engineering Environmental Information Management Center, and is located at the following address:

U.S. Department of Energy-Richland Operations Office
Administrative Record Center
345 Hills Street
Richland, WA 99352

This appendix is divided into subappendices: one for background results, one for each operable subunit, one for results from miscellaneous locations within the operable unit, and one for target parameters analyzed for and not detected. Results within each subappendix are presented as either surface or subsurface results. Surface soils are considered to be those within uppermost 0.6m (2ft) of the soil column.

This page left intentionally blank.

APPENDIX I
DATA QUALIFIERS

ORGANIC DATA QUALIFIERS

U The material was analyzed for, but was not detected. The associated value is the sample quantitation limit (SQL).

J The associated value is an estimated quantity.

UJ The material was analyzed for, but was not detected. The SQL is an estimated quantity.

R The data are unusable.

ND Corresponding TIC was not detected.

NR Not reported and/or not requested.

INORGANIC DATA QUALIFIERS

U The material was analyzed for, but was not detected above the level of the associated value.

J The associated value is an estimated quantity.

UJ The material was analyzed for but was not detected. The associated value is an estimate and may be inaccurate or imprecise.

R The data are unusable.

NR Not reported and/or not requested.

E Value is estimated due to matrix interference.

N Spiked sample recovery not within control limits.

S Reported value was determined by the Method of Standard Additions (MSA).

W Post-digestion spike for furnace AA analysis is out of control limits, while sample absorbance is <50% of spike absorbance.

---

* Duplicate analysis was not within control limits.
\+ Correlation coefficient for MSA was <0.995.

This page left intentionally blank.

Other Organics	ethylene glycol	2000
Asbestos	asbestos fibers	1%

APPENDIX J
WELL INVENTORY

The purpose of this appendix is to provide information on ground-water wells located in the 1100-EM-1 operable unit vicinity. Table J-1 lists wells on file with the Washington State Department of Ecology. Table J-2 lists wells identified by McGahn (1989) and Advanced Nuclear Fuels Corp. (1990). Figure 3-36 in the text shows the location of the wells listed in this appendix.

McGhan, V.L., 1989, *Hanford Wells*, PNL-6907, Pacific Northwest Laboratory, Richland, Washington.

APPENDIX K
CITY OF RICHLAND WELL FIELDS WATER USE RATES

The purpose of this appendix is to provide City of Richland Water System Reports for 1988 and 1989. The two columns circled represent water production rates, million gallons per day, for the 3,000 Area wells and the Filter Plant. The monthly total production rates for the City of Richland Well Field and Filter Plant are presented in Figure 4-43 in the text.

APPENDIX L

RESULTS OF SLUG TESTING IN 1100-EM-1 OPERABLE UNIT

In the course of the ground-water investigation of the 1100-EM-1 Operable Unit, a series of slug tests were conducted in the new wells constructed as part of the investigation. The slug tests involved both injection and withdrawal tests: the injection tests were conducted by inserting a solid cylindrical rod into the well to cause a brief rise in the water level in order to measure the subsequent decline. In the withdrawal tests the cylindrical rod was pulled out of the well to cause a brief decline in the water level with measurements made of the subsequent rise. A pressure transducer and data logger were used to measure and record the change in water levels with time.

Review of the field data indicates that the insertion of the rod in the injection test caused oscillations of the water level such that the data were unsuitable for analysis. The withdrawal test data, however, were suitable for analyses after the first several hundredths of a second. Therefore only withdrawal test data were analyzed for estimates of hydraulic conductivity, K.

The withdrawal test data were analyzed by the method of Bouwer and Rice (Bouwer and Rice, 1976; Bouwer, 1989). As indicated in the title of the first paper referenced, the analysis is appropriate for partially penetrating wells in unconfined aquifers. The data from the data logger were reviewed and a graph of the log of the change in water level, y, vs. time, t, was generated. Data points in which the change in water level, y, were negative or zero were deleted, as were data points in which the change was significantly out of the range of rest of the test data; these data reflect the oscillations of the water level in the first few hundredths of a second of the test. Analyses of the data were carried out using an optimization algorithm (Kemblowski and Klein, 1989) based on the minimization of the square of the difference between the observed and calculated change in the water level.

Graphs of the test data, in the form of the logarithm of the change in water level, log y, vs. time, t, are presented on pages L-4 through L-21. A summary of the estimates of the hydraulic conductivity, K, obtained in the analyses is presented in the Table L.1. Two tests were conducted in wells MW 1, 8 and 15, and one test in the other wells. In constructing the straight line section on the semi-log plot of y vs. t, a section of short time duration early in the test was neglected, if observed, as it was deemed to represent drainage from the sand pack as described in Bouwer, 1989. However in some wells two straight line sections were observed on the log y vs t graph. At this time we are not sure whether this represents additional drainage of the sand pack or another zone in the aquifer. Therefore Table L.1 indicates results for the hydraulic conductivity in feet per day for early time and,

if appropriate, late time. As an aid in the interpretation of the test results, the type of screen is noted in the table since some wells were constructed with a 10 slot stainless steel channel pack screen with a 20 - 40 filter, while other wells had a standard wire-wound stainless steel screen. The standard screens were 10 slot with the exception of well MW 8 which has a 20 slot screen. Table L.1 also indicates the portion of the saturated and screened section estimated to be in the Hanford formation vs. that in the Ringold Formation.

Examination of Table L.1 reveals that there is a generally good correlation between slug test results and the formation contributing to flow in a particular well. That is, wells that are predominately or entirely screened in the Hanford formation tend to have higher values of K than those screened in the Ringold Formation. Also there is generally good correlation between hydraulic conductivity and the type of well screen. Wells with wire-wound screens tend to have values of K greater than wells with channel-pack screens. While these correlations may be described as being generally in good agreement, examination of Table L.1 indicates that this is not always the case. The results obtained in this series of slug tests suggest that hydraulic conductivity is a function of both the geology and type of well screen, and it is unclear as to which is the dominant factor.

Slug testing only provides an approximation of the hydraulic conductivity since only a small area around the well is influenced by the water level fluctuations in the well in the short time period encompassed in a slug test. A further complication is the possible damage to the formation during the construction of the well. In view of the limitations of the method, the results of the slug testing of the 15 wells are considered to be in reasonably good agreement. However, additional evaluation of the slug test method in comparison with longer term pump tests is required before confidence can be placed in the absolute values of the hydraulic conductivities determined from slug tests.

APPENDIX M
GROUND-WATER POTENTIAL MEASURMENTS

The purpose of this appendix is to present ground-water potential measurements made on March 2, March 5, and May 23, 1990. Interpretation of the data is discussed in Section 3.6.2.3.

This page left intentionally blank.

APPENDIX N
GROUND-WATER CHEMICAL ANALYTICAL RESULTS

Ground-water chemical analyses were completed by Weyerhaeuser Analytical and Testing Services, U.S. Testing Company, and HEHF. The Westinghouse Hanford Office of Sample Management provided the validated data summarized in this appendix. A complete set of data is available in the DOE-RL 1100-EM-1 Administrative Record. The DOE-RL 1100-EM-1 Administrative Record is managed by Westinghouse Hanford's Department of Engineering Environmental Information Management Center, and is located at the following address:

U.S. Department of Energy-Richland Operations Office
Administrative Record Center
345 Hills Street
Richland, WA 99352

APPENDIX N
DATA QUALIFIERS

ORGANIC DATA QUALIFIERS

U The material was analyzed for, but was not detected. The associated value is the sample quantitation limit (SQL).

J The associated value is an estimated quantity.

UJ The material was analyzed for, but was not detected. The SQL is an estimated quantity.

R The data are unusable.

ND Corresponding TIC was not detected.

NR Not reported and/or not requested.

INORGANIC DATA QUALIFIERS

U The material was analyzed for, but was not detected above the level of the associated value.

J The associated value is an estimated quantity.

UJ The material was analyzed for but was not detected. The associated value is an estimate and may be inaccurate or imprecise.

R The data are unusable.

NR Not reported and/or not requested.

APPENDIX O

ORGANIC TENTATIVELY IDENTIFIED COMPOUNDS

The analysis of organic compounds using GC/MS techniques (EPA Methods 8240 and 8270) are capable of detection and identifying compounds in addition to parameters requested within the Target Compound List (TCL). These additional compounds are called tentatively identified compounds (TICs) because instrument calibration was not specific. The associated analytical concentrations can only be considered semi-quantitative. When the analyst felt too great an uncertainty in TIC identification, the TIC was called "unknown".

The laboratory chemical analytical results from Phase I 1100-EM-1 contained numerous TICs especially for EPA Method 8270 semi-volatile organic analyses. These TICs need to be evaluated, case blank adjusted and background adjusted to determine whether a specific organic compound is potentially a contaminant associated with 1100-EM-1 Operable Unit. This appendix describes the procedures used in TIC evaluations and adjustments. Tentatively identified TICs and unknown TICs were treated separately and in a different manner. Soil TICs are evaluated first in this appendix with ground-water TICs following.

SOILS

Appendix I presents all of the soil chemical analytical results including the TICs. All TICs in Appendix I are reported with a retention time (RT) and estimated concentration.

Tentatively Identified TICs:

The tentatively identified TICs where initially evaluated by several criteria in accordance with Bleyler (1988). This evaluation resulted in the elimination of many TICs based on at least one of the following criteria:

1. The identification of the compound (or similar group of compounds) is not consistent and retention time shift is greater than 0.3%.

2. The compound is or is suspected to be an artifact of a common laboratory contaminant such as:

    - A common lab contaminant: carbon dioxide, siloxanes, ethers, hexane, freon-113, freon-TF or phthalate esters at levels less than 100 ppb (water) or 4000 ppb (soils).

    - A common solvent preservative or derivative: cyclohexene, cyclohexanone, cyclohexenone, cyclohexanol, cyclohexenol, chlorocyclohexene and cyclocyclohexanol.

    - Aldol reaction products of acetone: 4-hydroxy-4-methyl-2-pentanone, 4-methyl-2-penten-2-one and 5,5,-dimethyl-2(5h)-furanone.

3. The compound is a TCL compound, tentatively identified in the wrong fraction [such as PCB identified in the BNA fraction].

4. The TIC compound is not sufficiently elevated above an associated case or SDG blank [compound less than or equal to 5 times the amount in the associated blank(s)]. Table O-1 lists the maximum concentration of identified TICs detected in a blank sample associated with soil samples.

5. The TIC compound is not sufficiently elevated above the Contract Required Detection Limit (CRDL) for like or similar TCL compounds [CRDLs ranging from 0.3 to 2 mg/kg (using one significant figure accuracy) in semi-volatile fractions].

The next procedure applied to identified TICs was to eliminate TICs that are also identified in Background soil samples at approximately similar concentrations. Table O-2 lists the maximum concentration for identified TICs detected in Background surface and subsurface soil samples.

The final remaining tentatively identified compounds in soils are listed in Table O-3.

Unknown TICs:

Evaluation and adjustments for final validation of chemical analytical data of unknown (unidentified) TICs requires a different approach than for identified TICs. The guidelines for evaluating organic analyses (Bleyler, 1988) does not provide a specific procedure for validation of unknown TICs. The approach used involves determination of the variance in retention time (RT) for identified TICs, listing all unknown TICs detected in blank samples, then determining "RT windows" that exist between blank TICs. Unknown TICs in soil samples that have retention times within the "RT windows" cannot be associated with a blank.

Since retention times vary for a compound on different instruments or at different times on the same instrument, the variation in RT for TICs is necessary. Identified TICs for all soil samples and associated blanks were tabulated by compound then RT (separately for volatiles and semi-volatiles). The tolerance interval (at 95% probability for a 95% quantile) was calculated for each identified TIC that was detected at least twice. Linear regression analyses was conducted to determine the relationship between average RT and the size of the tolerance for the degrees of freedom. The linear relationship of best fit had the following slopes, tolerance interval intercept and correlation coefficients:

	Volatiles	Semi-Volatiles
Slope	2.58	0.426
TL Intercept	-7.02	-1.04
Correlation Coef.	0.99	0.34
Number of Pairs	4	48

The "RT" windows were determined for volatile and semi-volatiles organic TICs in soils assuming the above linear relation on all operable unit blank unknown TICs associated with soil samples. The only resulting "RT window" existing for volatile unknown TICs is >46.5; whereas, resulting "RT windows" for semi-volatile organics exist :<4.6; between 18.0-22.76; and

>42.9. There were no volatile organic unknown TICs in soil; samples having a RT greater than 46.5. Table O-4 lists all semi-volatile organic TICs in soil samples that have RTs within the specified windows. These unknown TICS represent organic compounds that are present in soil samples that are not contained in associate blank samples at the given probability.

The final procedure was to compare the unknown TICs that were presented in Table O-4 to unknown TICs detected in soil background samples. There is a semi-volatile organic unknown TIC within the "RT window" between 18.0-22.76 in sample AH224S. This unknown TIC eliminates the "RT window", therefore, no unknown TICs are considered potential contamination at the given probability.

GROUND WATER

First Ground Water Monitoring Period

Ground-water samples contained only a few TICs. Table O-5 lists all tentatively identified and unknown TICs that were observed in samples from the first ground water monitoring period. All identified TICs (except 1,1,2-trichloro-1,2-ethane) in Table O-5 are eliminated from further consideration because they are suspected to be an artifact of a common laboratory contaminant. Specifically, freon is a common laboratory contaminant, the cyclo-siloxanes are associated with column bleed and 2-chloro-phosphatethanol is a breakdown product of solvent preservatives. The only remaining identified TIC is 1,12-trichloro-1,2-ethane which was detected in two ground-water samples during volatile organic analyses at an estimated concentration of 3 and 4 µg/l. These concentrations are below the maximum contract required detection limit (CRDL) of 10 µg/l for volatile organics in water. Five unknown TICs were detected during semi-volatile organic analyses within ground-water samples which occurred at RTs of: 10.55; 10.94; 22.94; 23.87; and 26.46. The maximum relative concentration of these unknown TICs in groundwater was 8.6 µg/l. Since this concentration is below the maximum contract required detection limit (CRDL) of 50 µg/l for semi-volatile organic analyses of water samples, these unknown TICs were eliminated from further consideration. Therefore, the first ground water monitoring period did not detect organic TICs that could be considered potential contamination.

Second Ground-Water Monitoring Period

Ground-water samples from the second monitoring period contained only a few organic TICs which are presented in Table O-6. One volatile organic TIC, butanoic acid methyl ester, was tentatively identified, but is eliminated because it is considered to be a common laboratory solvent preservative. One semi-volatile organic TIC was tentatively identified as ethanol, 2 - chloro - phosphate and is eliminated from further consideration because it is also a common laboratory solvent preservative. Five unknown TICs were detected during semi-volatile analyses within ground-water samples which occurred at RTs of 6.5, 29.12, 32.24, 33.67, and 35.14. The maximum relative concentration of these unknown TICs in ground water was 13 µg/l. Since this concentration is below, the maximum contract required detection limit (CRDL) of 50 µg/l for semi-volatile organic analyses in water, these unknown TICs were elimimated from further consideration. Therefore, the second ground-water monitoring period did not detect any organic TICs that could be considered potential contamination.

APPENDIX P
SOIL CHEMICAL ANALYTICAL RESULTS ABOVE BACKGROUND SOIL CONCENTRATIONS

The purpose of this appendix is to present the Soil Chemical Analytical Results that were above background soils concentrations in Tables. Section 4.4 in the text describes the methods used to determine background soil concentrations. This appendix is organized by operable subunit-surface and subsurface results.

This page left intentionally blank.

APPENDIX Q

TOXICITY PROFILES FOR CONTAMINANTS OF POTENTIAL CONCERN AT THE 1100-EM-1 OPERABLE UNIT

Information for each contaminant of potential concern identified at the 1100-EM-1 Operable Unit is provided in this appendix. Toxicity profiles are also provided for trichloroethene and nitrate which are the two characterized contaminants of the ground-water plume originating upgradient from the Horn Rapids Landfill. The categories of information include:

- general background information
- exposure routes
- acute toxicity
- chronic toxicity
- carcinogenicity
- toxicity values and supporting information.

Data sources for the information provided in the appendix are from EPA documents and standard reference texts. See Appendix Q References.

ARSENIC

Arsenic is a common element found in the earth's crust usually in the form of arsenic bearing minerals. It is difficult to characterize as a single element because its chemistry is very complex. Elemental (metallic) arsenic is a relatively non-toxic steel gray metal which is fairly rare in nature. Trivalent and pentavalent forms are widely distributed in nature as both inorganic and organic compounds. The trivalent form is more toxic than the pentavalent form, and the inorganic is typically more toxic than the organic form which is rapidly eliminated. Soil levels range from 1 to 50 mg/kg but are usually less than 10 mg/kg. In the soil, compounds revert to arsenates which are held by clay soils and are not readily available for plant uptake. Arsenic has found use as pesticides, herbicides, wood preservatives, pigments, and medicinal agents.

Depending on the chemical species, arsenic can be toxic via all routes of exposure. Acute arsenic poisoning is usually the result of homicidal, suicidal, or accidental ingestion of inorganic arsenicals. Arsenic is well absorbed from the gastrointestinal tract. Symptoms include constriction of the throat, stomach pain, vomiting, fever, cardiac disturbances, and watery diarrhea usually within 4 h of exposure. If the amount is sufficiently high (100-200 mg), death as a result of severe fluid loss and shock may occur within 24 to 48 h. Toxicity in humans and animals results from the interaction of arsenic with sulfhydryl groups in essential proteins.

Chronic exposures can produce toxic reactions in the skin, mucous membranes, gastrointestinal tract, and central nervous system (CNS). Peripheral vascular disease (gangrene) related to a cumulative effect can occur. Liver injury has also been associated with chronic exposure. Arsenic has a predilection for skin and concentrates in hair and nails. Long term exposure to arsenic compounds can result in hyperpigmentation, hyperkeratosis (thickening, drying, and cracking of the skin and growth of warts), and skin cancer. Skin cancer has been primarily associated with ingestion of drinking water containing high levels of arsenic. Chronic exposure through inhalation of arsenic compounds can produce weakness, loss of appetite, nausea, occasional vomiting and diarrhea, and lung cancer.

The oral RfD for arsenic provided in HEAST is 1.0E-03 mg/kg/d and the adverse effects of concern are keratosis and hyperpigmentation. This RfD is currently under review. Arsenic is a confirmed human carcinogen (EPA weight-of-evidence-classification A) known to produce lung cancer from inhalation and skin cancer from ingestion of drinking water. The inhalation SF listed in IRIS is 5.0E+01 $(mg/kg/d)^{-1}$ and is based on excellent exposure assessment, using air monitoring and some biomonitoring, in large populations of smelter workers. The carcinogenic risk associated with ingestion of inorganic arsenic has been the focus of much debate. A mean unit risk of 0.00005 $(ug/L)^{-1}$ has been recommended by EPA (1990). (The unit risk is defined as the risk associated with a lifetime consumption of inorganic arsenic in drinking water.) Applying standard exposure assumptions, this unit risk corresponds to an estimated oral potency slope factor of 1.7 $(mg/kg/d)^{-1}$. This proposed value, reflecting the most recent opinions regarding the mechanism of action of ingested inorganic arsenic, is used to assess the carcinogenic oral exposure to arsenic. The unit risk is based on human studies showing a definite dose-response relationship between the consumption of drinking water and the development of skin cancer.

Recommended occupational air exposure limits for arsenic are also available. The American Conference of Governmental Industrial Hygienists (ACGIH) has established a time-weighted-average (TWA) threshold limit value (TLV) of 0.2 mg/M^3 (as arsenic), for arsenic and soluble compounds, in situations other than the production of arsenic. The Occupational Safety and Health Administration (OSHA) has established a TWA permissible exposure limit (PEL) of 0.1mg/M^3 for exposure to inorganic arsenic (29 CFR 1910.1018). The National Institute for Occupational Safety and Health (NIOSH) recommended exposure limit (REL) is 0.002 mg/M^3.

The maximum contaminant level (MCL) for arsenic in drinking water is 0.05 mg/L and the maximum contaminant level goal (MCLG) is 0.05 mg/L. The Human Water Quality Health Criteria (HWQHC) for arsenic based on water and fish consumption is 2.2E-06 mg/L.

BIS (2-ETHYLHEXYL) PHTHALATE

Bis (2-ethylhexyl)phthalate (BEHP) is a chemical used to make plastics more flexible. This compound is a constituent of numerous consumer products including rainwear, flooring, shower curtains, and medical tubing. This substance and other phthalate-ester plasticizers have been found to be general contaminants in virtually all soil and water ecosystems. Insoluble phthalate esters complex with fulvic acid components of humic substances in soil. Fulvic acid functions as a solubilizer for the phthalates and thus serves to mediate the mobilization and transport of phthalates in soil and water. The widespread occurrence of phthalates such as BEHP has produced concern regarding their toxicity.

Bis (2-ethylhexyl)phthalate is well absorbed orally and there is evidence of some absorption through the dermal and inhalation routes of exposure. Acute toxicity is low by all routes of exposure. No effects have been observed from a single 5,000 mg oral dose in humans while 10,000 mgs produced only some gastrointestinal distress.

Animal studies indicate the liver and testes are target organs for adverse effects from chronic exposure to BEHP. This compound has also been reported to affect male and female reproductive capacity and oral ingestion has produced birth defects in laboratory animals. The chronic oral RfD is 2E-02 mg/kg/d. A 1953 study is cited by IRIS in which the observed critical effect was an increase in relative liver weight. Confidence in the RfD is medium although sufficient numbers of animals were tested and multiple endpoints measures, only two dosages were utilized for less than lifetime exposures to determine the RfD. Corroborating chronic animal bioassays, however, do support this RfD.

Bis (2-ethylhexyl)phthalate is considered to be a probable human carcinogen (EPA B2 classification) based on a 1982 National Toxicology Program (NTP) oral study in animals. A statistically significant, dose-dependent increase in liver tumors was observed in male and female mice and female rats receiving BEHP in food. The oral SF listed in IRIS is 1.4E-02 (mg/kg/d)$^{-1}$. A potential source of variation in the NTP study that could effect the slope factor is the use of an intake based on standard food consumption rates rather than administration of a known dose. Evidence for carcinogenicity of BEHP in exposed human populations is inadequate.

The ACGIH recommended TLV-TWA for BEHP is 5 mg/M^3 and a TLV short-term exposure limit (STEL) of 10 mg/^{3}. The NIOSH REL is reduction of the exposure to the lowest feasible

concentration because of the cancer-causing potential of BEHP. The OSHA PEL for BEHP is 5mg/M^3.

The HWQHC for BEHP, based on water and fish consumption, is 1.5E+01 mg/L.

CHLORDANE

Chlordane is a man-made chemical used prior to 1983 as an agricultural pesticide and until 1988 for termite control. It is a multicomponent mixture with alpha- and gamma-chlordane as the primary components. Exposure to chlordane is possible via all routes including inhalation, ingestion, and dermal absorption. Chlordane is extremely persistent in the environment and can be toxic to wildlife.

In humans, acute toxicity from inhaling high concentrations of chlordane vapors is manifested as headache, irritation, confusion, and gastrointestinal complaints. Similar adverse effects have occurred after dermal contact with heavily contaminated soil for several hours. Suicidal or accidental ingestion of large quantities of chlordane have produced liver damage, seizures, and death. The acute lethal dose in man is not known, but has been estimated to be 25 to 50 mg/kg by ingestion.

Chronic toxic effects have not been identified in workers who produced or used chlordane. The critical effect in a 1983 chronic feeding study in rats was regional liver hypertrophy in female rats. Based on this study, the EPA oral RfD reported in IRIS is 6E-05 mg/kg/d. Confidence in this RfD, however, is low. The database lacks adequate reproductive studies, testing in multiple mammalian species, and inadequate assessment of sensitive endpoints. Chlordane is known to bioaccumulate in body fat with chronic exposure.

The EPA classifies chlordane as a B2 probable human carcinogen. Results of a 1977 National Cancer Institute (NCI) study indicate a significant dose-response increase in liver tumors in mice. These data are supported by additional animal studies. However, evidence from human studies to document the carcinogenicity of chlordane is insufficient. An oral SF for chlordane of 1.3E+00 (mg/kg/d)$^{-1}$ is reported in IRIS. The inhalation SF published in IRIS is 1.3E+00 (mg/kg/d)^{1}.

THE OSHA established TWA-PEL for chlordane is 0.5 mg/M^3 with a recommendation to protect skin in order to limit dermal absorption of chlordane. This occupational exposure limit is the same as that recommended by NIOSH and the ACGIH. However, the ACGIH further recommends a TLV-STEL of 2 mg/M^3. The air concentration of chlordane that is immediately dangerous to life and health (IDLH) is 500 mg/m^3.

The drinking water MCLG for chlordane is 0 mg/L based upon carcinogenic effects. The HWQHC for chlordane, based on water and fish consumption, is 4.6E-07 mg/L.

CHROMIUM

Elemental chromium does not exist naturally in the environment, but is found primarily as a part of chromite ore. In compounds, this element exists in one of three valence states, +2, +3, or +6. The trivalent form is an essential human micronutrient involved in carbohydrate metabolism. Adverse effects have not been associated with the trivalent form. The hexavalent

form is important industrially (typically in the form of chromates) and has been associated with serious toxicities.

Hexavalent chromium is mobile in soil, but under aerobic, acidic soil conditions, it is reduced to trivalent chromium which readily precipitates with carbonates and hydroxides in the soil. Hexavalent chromium is toxic to plants. However, plants actually tolerate relatively high levels of chromium in the soil and do not accumulate significant amounts.

Human toxicity has been associated with hexavalent chromium by all routes of exposure. Hexavalent chromium is irritating and short-term high exposures can result in adverse effects at the site of contact, whether it is the skin, gastrointestinal tract, or respiratory tract. Such contact can result in coughing, wheezing, irritation and perforation of the nasal mucosa, and pulmonary edema. Kidney and liver damage have also been associated with acute exposures. Hexavalent chromium is a potent sensitizer causing allergic reactions in the lungs, nasal passages, and skin. Long term exposure to airborne hexavalent chromium higher than the natural environment is known to produce lung and respiratory tract cancer in humans.

The EPA has determined the oral RfD for hexavalent chromium as 5E-03 mg/kg/d based on a drinking water study in rats. The confidence in this RfD is low and no critical effects were observed because of poor study design.

Hexavalent chromium is classified by EPA as a known human carcinogen (weight-of-evidence classification A) by inhalation exposure. A 1975 study is cited in IRIS and multiple supporting studies from other countries also exist to demonstrate a dose-response relationship between hexavalent chromium exposure and lung tumor production. The inhalation SF is 4.1 E+01 $(mg/kg/d)^{-1}$. No evidence exists to indicate chromium is carcinogenic by the oral route.

Occupational air exposure limits for chromium are based on the toxicities associated with different forms. For carcinogenic forms of hexavalent chromium, the NIOSH TWA recommendation is 0.001 mg/M^3. The OSHA PEL for chromium metal is 1 mg/M^3 and the IDLH is 500 mg/M^3.

The drinking water MCL for total chromium is 0.05 mg/L and the MCLG is 0.12 mg/L. For water and fish consumption, the HWQHC is 0.005 mg/L.

NITRATE

As a class, nitrate compounds are a variety of chemicals used as explosives, medications, dyes, food additives, and as numerous other industrial products. The nitrate form of nitrogen is very water soluble and is highly mobile in water and soil. Concern has arisen over the accumulation of these compounds in the environment.

Exposure can result primarily from ingestion of contaminated water, but may also be associated with ingestion of soils and dermal contact with contaminated media. Toxicity is related to the specific compound. However, as a class, acute exposure to nitrates can produce headache, decreased blood pressure, abdominal pain, dilation of blood vessels, and methemoglobinemia. Chronic exposure may result in weakness, general depression, headache, and mental impairment.

Human toxicity to nitrates in water is due to the conversion of nitrate to nitrite which results in the oxidation of hemoglobin to methemoglobin. Animals are a poor model for methemoglobin formation because many species lack nitrate-reducing bacteria. Infants, however, are particularly susceptible to nitrates due to their high gut content of nitrate-reducing bacteria, their lower enzymatic capacity to convert methemoglobin to hemoglobin, and the presence of hemoglobin F, which is more susceptible to oxidation.

The chronic RfD for nitrate is 1.0E+00 mg/kg/d based on a study of infants chronically exposed to nitrate in drinking water. The observed adverse effect was methemoglobinemia. No uncertainty factors have been applied to this intake because the RfD was determined from epidemiological studies in the most sensitive human population. Thus, confidence in the RfD is high. Nitrate has not been evaluated for carcinogenic potential.

Occupational exposure limits for nitrate in air are not established. The MCL and the MCLG for nitrate in drinking water is 44 mg/L.

POLYCHLORINATED BIPHENYL

Polychlorinated biphenyls are very stable materials that contain 12 to 68% chlorine and are extremely persistent in the environment. Because of their low flammability and stability, PCBs have been used as insulating materials in electrical transformers and capacitors, as plasticizers in waxes, in paper manufacturing, and for a variety of other industrial purposes. The diversity of their use patterns, the large quantities used, and their stability has led to widespread occurrence of these compounds in soil and water. Polychlorinated biphenyls have been banned from use since 1978, but are still found in older electrical equipment and as contaminants in the environment. All PCBs are mixtures of chlorinated congeners, but the exact nature of these mixtures is unknown. Arochlor 1260 and Arochlor 1254 are commonly recognized PCB products. The last two digits in the number indicate the percentage of chlorine in the compound (i.e., 60 and 54% respectively).

Exposure to PCBs can occur from inhaling PCB-contaminated particulates, dermal absorption, or ingestion of contaminated food, soil, or water. Toxicity by all routes of exposure is similar. However, because of high public awareness of PCBs, in large part due to their extensive publicity, concern about exposure may far outweigh documented human toxicity.

Skin irritation can occur with acute and chronic exposure. A severe and disabling form of acne called chloracne is the primary dermal effect. Chronic toxicity studies in animals have suggested that PCBs can cause respiratory tract impairment, neurotoxicity, liver damage, birth defects, and cancer. Polychlorinated biphenyl congeners vary in their potency for producing biological effects, but little is known about which congeners may be responsible for the effects and to what extent the effects occur in humans.

The EPA does not currently provide oral or inhalation RfDs for PCBs in IRIS or HEAST. Polychlorinated biphenyls as a group (not as specific congeners or total chlorine mixtures) are considered probable human carcinogens because of data in animals indicating increased liver cancer in exposed animals. However, the commercial preparations used may not be representative of actual mixtures of congeners found in the environment. There is inadequate but suggestive evidence that PCBs may also cause liver cancer in humans by all routes of exposure. The EPA oral SF listed in IRIS is 7.7 $(mg/kg/d)^{-1}$. This slope factor is based on a 1985

study in rats showing a sequential progression of liver lesions to liver cancer during the natural life of the rat. The EPA carcinogenicity classification for PCBs is B2 (probable human carcinogen).

Occupational exposure limits for polychlorinated biphenyls are based on the chlorine content of the compound. Both OSHA and the ACGIH recommend a TWA for 54% polychlorinated biphenyls of 0.5 mg/M^3. The NIOSH recommendation for an occupational exposure limit is 0.001 mg/M^3. This level is the minimum reliably detectable concentration using the recommended sampling and analytical methods. Skin precautions are also recommended to prevent dermal absorption.

Based on water and fish consumption, the HWQHC for polychlorinated biphenyls is 7.9E-07 mg/L.

TETRACHLOROETHENE

Tetrachloroethene, also known as perchloroethylene and tetrachloroethylene, is a nonflammable liquid solvent used for dry cleaning fabrics and for metal degreasing operations. When tetrachloroethene evaporates, it produces an ether-like odor. However, it is relatively resistant to hydrolysis and biodegradation and thus persists in the environment. Tetrachloroethene is moderately to highly mobile in soil and susceptible to significant leaching.

The primary route of exposure to tetrachloroethene is through inhalation of vapors. Ingestion may occur from contaminated water. Dermal absorption is limited because tetrachloroethene does not penetrate intact skin to any great extent. The principal target organs are the CNS, liver, and kidney. Acute exposure to tetrachloroethene in confined, poorly ventilated areas, can produce dizziness, headache, confusion, nausea, and difficulty in walking. These effects are rapidly reversed when the individual is moved to clean air. The effects of long-term, low level exposure is not as well understood. Studies in animals suggest liver and kidney damage, birth defects, leukemia, and liver cancer may occur.

The oral RfD provided in IRIS for tetrachloroethene is 1E-02 mg/kg/d. The critical adverse effects found in animal studies used to determine the RfD were liver damage in mice and weight gain in rats. No inhalation RfD is currently available. Confidence in this RfD is only medium because of a good overall database but insufficient reproductive studies.

The carcinogenicity of tetrachloroethene is under review and a classification of B2 (probable human carcinogen) has been proposed. An oral SF is of 5.1E-02 (mg/kg/d)$^{-1}$ is published in HEAST. The inhalation SF is 3.3E-03 (mg/kg/d)$^{-1}$. Currently, epidemiological studies suggest an association between tetrachloroethene and an increased cancer risk but the human studies provide no good quantitative exposure information and involve exposure to other chemicals. Thus, the association is inconclusive.

The occupational exposure limit for tetrachloroethene recommended by OSHA is 170 mg/M^3. The currently recommended ACGIH exposure limits are a TWA of 340 mg/M^3 and an STEL concentration of 1,360 mg/M^3. The NIOSH recommendation is to minimize workplace exposure concentrations because this substance is a potential carcinogen. The IDLH concentrations is 3,400 mg/M^3.

The drinking water MCLG for tetrachloroethene is 0 mg/L. The HWQHC for water and fish consumption is 0.0008 mg/L.

1,1,1-TRICHLOROETHANE

1,1,1-Trichloroethane, also known as methyl chloroform, is a halogenated hydrocarbon used primarily as a solvent because of a favorable combination of chemical, physical, flammability, and toxicologic properties. Although 1,1,1-trichloroethane is probably the least toxic chlorinated solvent, careless use, high volatility, and poor disposal practices have contributed to the potential human and environmental concerns.

Acute exposure to TCA can produce CNS depression. Inhalation of 1,600 mg/M^3 by humans has produces no untoward response while inhalation of 5,400 to 10,800 mg/M^3 for 60 min can produce eye and nasal irritation and minor CNS impairment. The inhalation of 100,000 mg/M^3 for 60 min can produce anesthesia, cardiac sensitization to epinephrine, and possible death. Chronic, industrial exposure to 1,1,1-trichloroethane over 6 yr did not demonstrate liver toxicity or cardiac toxicity in humans. Some studies have suggested that animals exposed to 1,1,1-trichloroethane may develop fatty livers and liver necrosis. However, no adverse effects were detected in a 6-mo inhalation study in guinea pigs on which the IRIS oral RfD is based. An older supporting study noted only slight growth retardation in chronically exposed animals. The oral RfD is 9.0E-02 mg/kg/d. Confidence in the RfD is medium to low because of a limited number of animals at each dose level, variable lengths of exposure, and few toxic endpoints were examined. No inhalation RfD is published in IRIS, but HEAST lists an inhalation RfD for 1,1,1-trichloroethane of 3.0E-01 mg/kg/d. The adverse effect noted for the inhalation RfD is hepatotoxicity.

Animal studies have not demonstrated carcinogenicity nor are there any human data reported to indicate that 1,1,1-trichloroethane is a human carcinogen.

The OSHA PEL TWA and the ACGIH TLV for 1,1,1-trichloroethane is 1,900 mg/M^3 with a STEL of 2,450 mg/M^3. The NIOSH REL is 1,910 mg/M^3 15 minute ceiling and an action level set at a TWA of 1,091 mg/M^3.

The drinking water MCL for 1,1,1-trichloroethane is 0.20 mg/L and the MCLG is 0.20 mg/L. Based on water and fish consumption, the HWQHC is 18.4 mg/L.

TRICHLOROETHENE

Trichloroethene (also known as trichloroethylene) is a colorless liquid with an odor similar to ether or chloroform. This chemical is a man-made solvent used for degreasing metal parts, extracting caffeine from coffee, and in numerous consumer products such as typewriter correction fluid, paint removers, and spot removers.

Trichloroethene readily moves through soil and groundwater. Ingestion of contaminated water and inhalation of volatilized trichloroethene are the chief sources of exposure. Absorption is not significant from skin contact with this solvent.

Acute oral toxicity in humans is low. Death has occurred from an ingested dose of 70 mg/kg. Acute effects from inhalation of trichloroethene are associated with the central

nervous system (dizziness, headache, sleepiness) and occur at a threshold of 436 to 592 mg/M^3. Extremely high, acute exposures may produce cardiac rhythm disturbances. In animals, chronic exposure to trichloroethene by inhalation and ingestion has produced liver and kidney damage and may affect reproductive toxicity.

Neither IRIS nor HEAST currently provide an RfD for trichloroethene and determination of an RfD is pending. Trichloroethene may induce lung cancer in animals when inhaled and may produce liver cancer in animals from oral administration. The EPA weight-of-evidence classification is B2 (probable human carcinogen) based on sufficient evidence in animals. The oral and inhalation SFs for trichloroethene have also been withdrawn from IRIS pending further review of carcinogenicity studies. However, HEAST provides an inhalation SF of 1.7E-02 (mg/kg/d)$^{-1}$ and an oral SF of 1.1E-02 (mg/kg/d)$^{-1}$.

The OSHA final rule limits for occupational exposure to trichloroethene and the currently recommended ACGIH exposure limits are a TWA of 269 mg/M^3 and an STEL of 1,070 mg/M^3. Because trichloroethene is carcinogenic, NIOSH recommends a TWA of 135 mg/M^3. The NIOSH recommendations are considered the level that can be achieved by existing engineering controls and technology. The IDLH concentration for trichloroethene is 5,380 mg/M^3.

The drinking water MCL for trichloroethene is 0.005 mg/L and the MCLG is 0 mg/L. Based on water and fish consumption, the HWQHC is 0.0027 mg/L.
