Key Words: Direct Push, Pore Water Extraction, Hydraulic Hammer Unit, SX Tank Farm, Vadose Zone, Extraction and Monitoring wells, Geophysical logging and Small diameter Bore Hole

Abstract: This report details field activities for using small diameter soil borings for extracting pore water from partially saturated sediments. Stage I included field activities to obtain additional information at prospective sites. Stage II includes collecting soil samples for identifying preferred test location and designing test equipment associated with monitoring systems. Stage III includes procurement and installation of monitoring system in four new soil borings.

COMPLETION REPORT FOR 241-SX TANK FARM DIRECT PUSH PORE WATER EXTRACTION**1.0 INTRODUCTION**

The U.S. Department of Energy assigned the River Protection Project (RPP) Washington River Protection Solutions, LLC (WRPS) Richland, Washington, to plan and conduct subsurface pore water extraction testing near the SX Tank Farm located in the 200 West Area of the Hanford Site. WRPS contracted EnergySolutions Government Group, Inc. (EnergySolutions) to perform the field activities required to gather information to support the testing actions and to provide design and operational support for conducting extraction testing. The results from the extraction testing are intended to refine the extraction system designs and provide guidance for the potential future use of these types of small diameter extraction systems for removal of contaminate load in subsurface sediments.

In accordance with RPP-PLAN-53808, *200 West Area Tank Farms Interim Measures Preliminary Investigation Work Plan*, this project was performed in three stages. Stage I included field activities to obtain additional information about three prospective test locations for the project. This involved pushing and logging three test locations to determine if the locations had sedimentary deposits of the correct nature with adequate moisture content for application of soil moisture extraction techniques. The second stage involved pushing boreholes adjacent to the logging boreholes, collecting samples, identifying a preferred test location, and designing the test equipment and associated monitoring system. The third stage of field work involved procurement and installation of the monitoring equipment, including the pushing of four boreholes at the selected test location.

Initial documentation for this project did not follow the terminology for the stages as identified above and in RPP-PLAN-53808. Field work for the first two stages was addressed in GG-NW-DOW-001, *Description of Work: SX Pore Water Extraction – Stage I*, Rev. 0 (see Appendix A). (Note: Although GG-NW-DOW-001 only calls out Stage I, it covers all field work for the activities that are referred to as Stages I and II in RPP-PLAN-53808. Field work for Stage III was addressed in PL-36472-OP-0002, *Description of Work – SX Pore Water Extraction – Stage III*, Rev. 0 (see Appendix B).

EnergySolutions was responsible for providing equipment and personnel to conduct the direct push activities, geophysical logging services, soil sample collection, and safety oversight. EnergySolutions also provided technical support, designed and performed a “falling head” test sequence, and prepared final reports. The following appendices contain copies of documentation generated during the performance of the above work scope. Where appropriate, the appendices are grouped into those covering Stages I and II and then those covering Stage III.

2.0 STAGES I AND II

2.1 SUMMARY OF ACTIVITIES

As stated above, the field work for this project was divided into three stages. Guidance documentation and preparation for field activities for the first two stages was addressed in GG-NW-DOW-001, *Description of Work: SX Pore Waster Extraction – Stage I*, Rev. 0 (Appendix A), and Job Hazard Analysis (JHA) GG-NWOP-RO-1858, *Hanford SX Tank Farm Pore Water Extraction Stage I*, which were released on January 2, 2013.

Mobilization to SX Farm began on January 8, 2013, with the transportation and staging of a direct push rig and equipment south of the SX Farm fence line. Field-related activities for Stages I and II were completed and all equipment was surveyed and released, or packaged for disposal, on March 27, 2013. There were 48 working field days during this period. There was an initial delay in job start for work package modification and release that delayed actual set up of the direct push equipment and commencement of probe placement until January 21 (nine working days elapsed time). Total delays due to lack of onsite support, industrial hygiene concerns, weather issues, and work package changes totaled approximately 20 working days (180 hours). See Appendix C for copies of the Drilling and Sampling Daily Work Records.

The early work delays are attributable in part to the long hiatus between field deployments (i.e., no field activities for Vadose Group from December 2011 until January 2013). Many of the

RPP-RPT-56849, Rev. 0

support personnel utilized for generation of the required job start documentation and field support had not previously been involved in direct push work. An additional delay of field activities occurred when the WRPS Environmental personnel requested vapor samples from the target extraction zones. The release of the work package for starting the job was delayed while the Industrial Hygiene Sampling Plan was prepared for inclusion into the package. During work activities, an additional delay of two days was encountered during the implementation of the field vapor sampling actions.

Figure 1 shows the three planned locations for investigation in Stages I and II. The initial scope included an exploration hole for use in gathering logging information and a sampling hole for collection of two to three soil samples at each planned location. In addition to the logging and sampling, “falling head” tests were planned to provide information related to the degree of wall compaction produced by the displacement of soils as the direct push is advanced. The falling head testing was proposed to provide information demonstrating the ability of the borehole wall to allow water influx and the changes in this rate of influx after surging /bailing and repetition of the falling head testing sequence. Section 2.5 describes the falling head tests in more detail

Of the three planned locations, the initial site (C8757) met refusal at 11.5 ft below ground surface (bgs) on three tries. This was interpreted to indicate that there was a significant area of subsurface debris at this location and further efforts in this area were abandoned. At the remaining two locations (C8759 and C8761), the exploration holes were driven to approximately 150 ft bgs and spectral gamma (with a combination lanthanum bromide /bismuth germinate oxide (LaBr/BGO) instrument) and neutron-neutron moisture log data were collected. Three sets of samples were collected in each of the two sampling boreholes, placed adjacent to the exploration boreholes, for a total of six discrete samples.

2.2 DIRECT PUSHING

Exploration hole placement and sampling was accomplished with the use of a hydraulic hammer system. Exploration boreholes were pushed using a 6.35 cm (2.5 in.) outside diameter (OD) x 4.45 cm (1.75 in.) inside diameter (ID) casing at predetermined locations to specified depths, or refusal.

After logging the exploration boreholes, the data was reviewed by WRPS personnel and sample locations and depths were selected. Sampling boreholes were then pushed, within 0.6-1 m (2-3 ft) of the exploratory holes, for sample retrieval at the selected depths.

2.3 GEOPHYSICAL LOGGING

EnergySolutions and Three Rivers Scientific conducted the geophysical logging data collection and analysis services on the exploration 6.35 cm (2.5 in.) probe boreholes. For the geophysical logging, a portable small diameter logging system was used to collect spectral gamma and moisture data from the bottom of the borehole to the ground surface. Calibration details, survey

RPP-RPT-56849, Rev. 0

results, and data interpretation, as well as copies of the collected and processed log data, for Stages I and II are provided in Appendix D.

2.4 SOIL SAMPLING

2.4.1 Sample Selection

Selection of specific zones for sampling at the two locations under investigation was based on the need to identify target areas for pore water extraction. Criteria were selected based on modeling results from the Pacific Northwest National Laboratory (PNNL) and subsurface data collected nearby in SX Tank Farm. The extraction zone required:

- A moisture content greater than 25% by volume.
- A grain size range composed primarily of fine to very fine sand and silt. (Course grained material and heavy clay zones are not conducive to extraction).
- A minimum thickness of 2+ feet of “uniform” grain size material.
- Measurable Tc⁹⁹ and/or nitrate values to assist in evaluation of the extraction productivity (if possible).

Based on review of the geophysical logs and comparison to nearby boreholes and direct push data from inside SX Tank Farm, two target zones (one in each exploration well) were selected for sampling. For well C8759 (sampling well C8760) the zone was 121 to 127 ft bgs and for C8761 (sampling well C8762) the target zone was 123 to 129 ft bgs. (See Appendix E for meeting minutes from sample selection meeting).

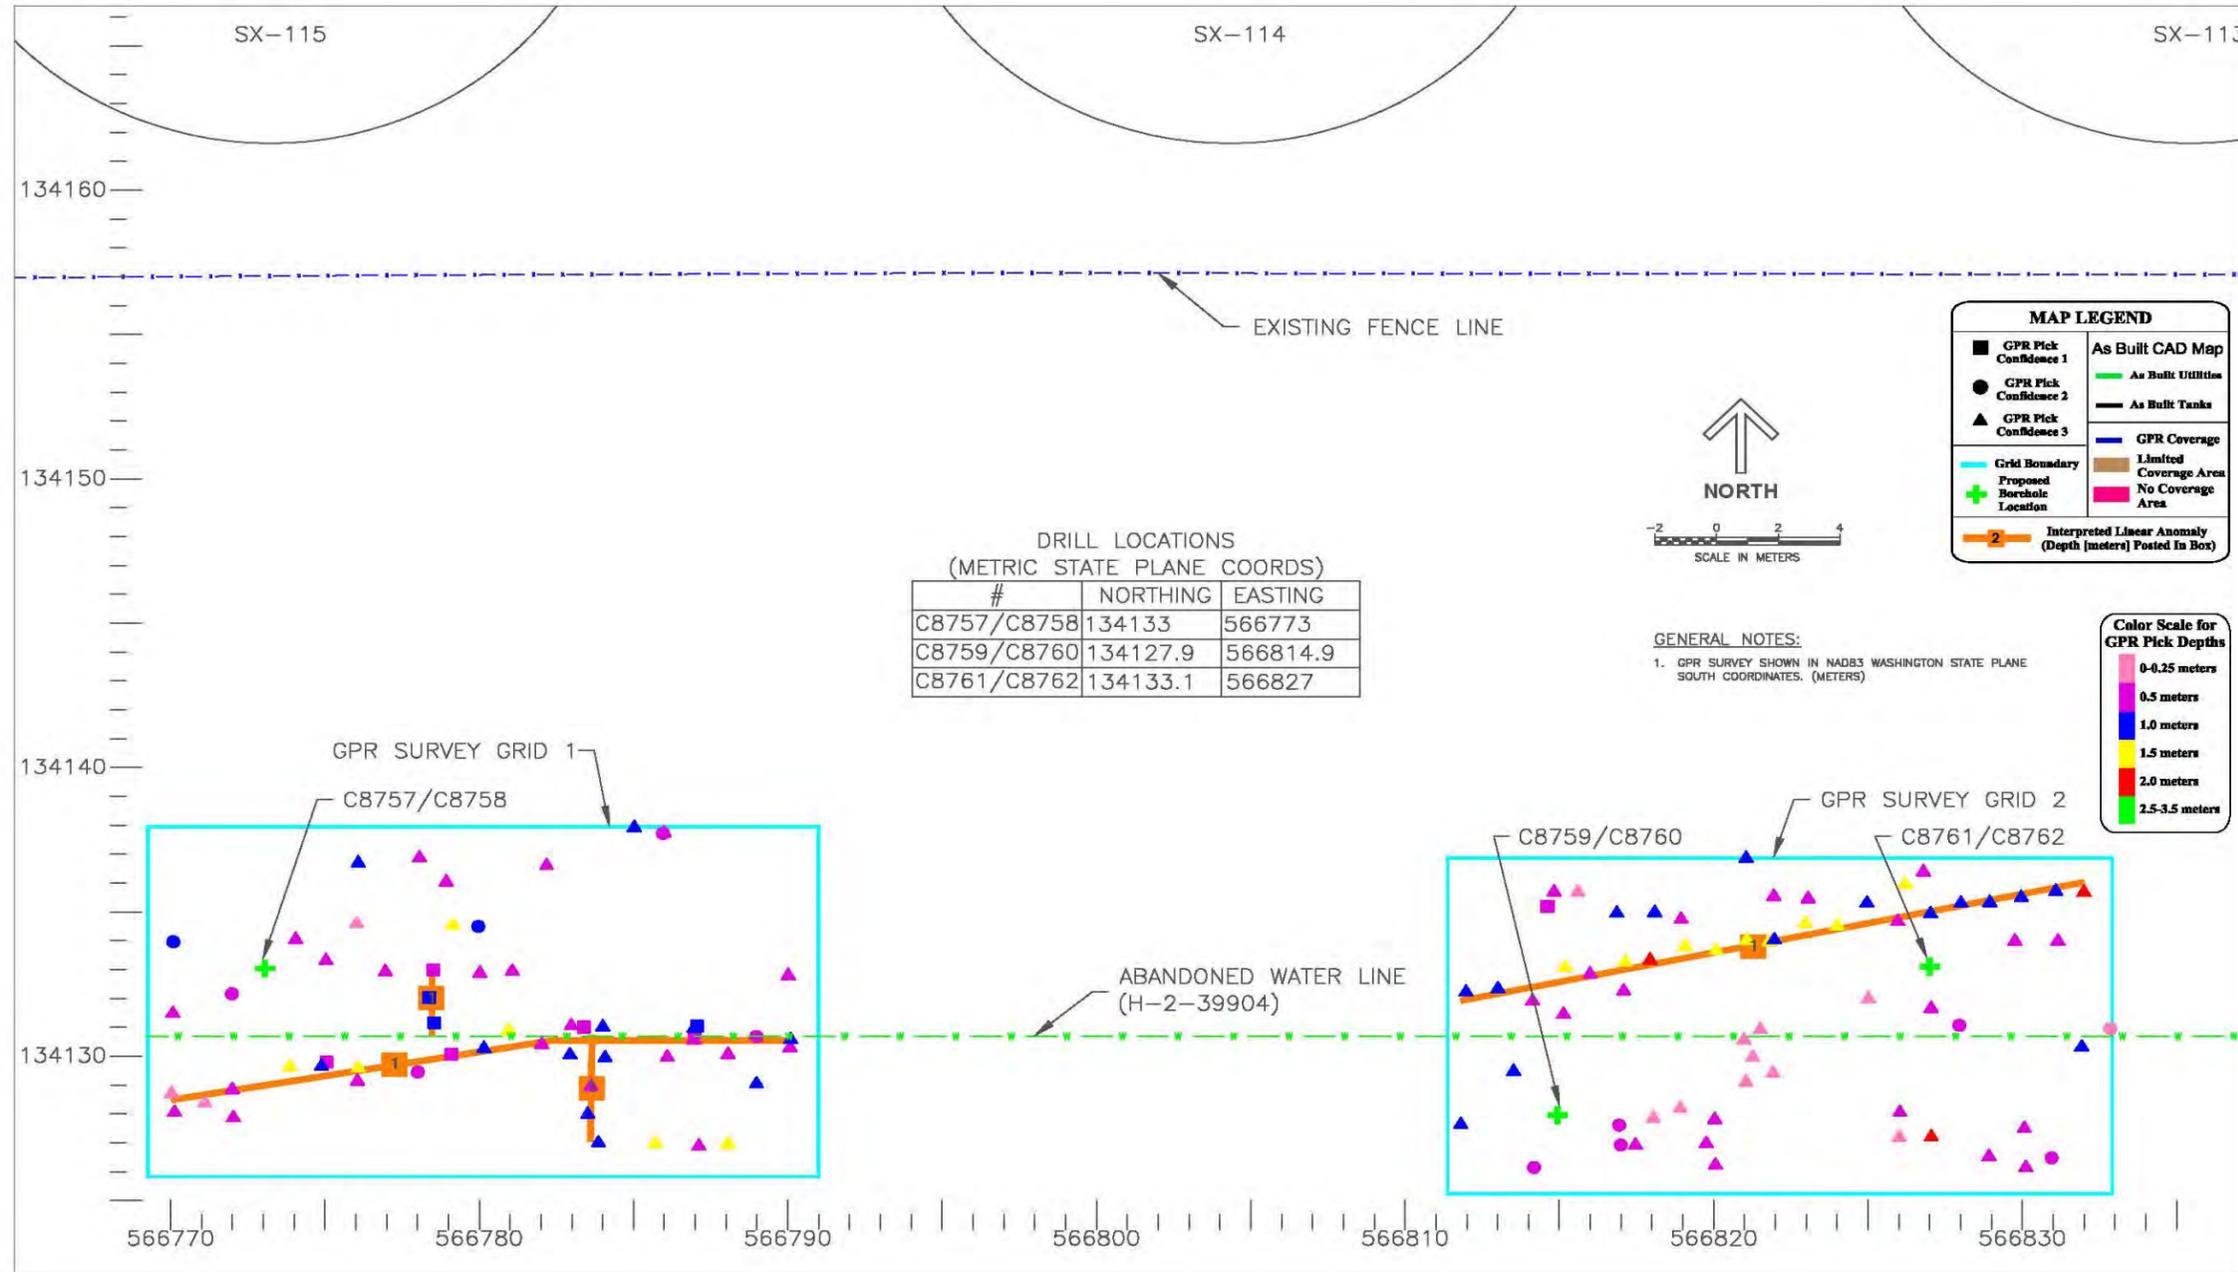

2.4.2 Sample Collection

Soil sampling with the rotary hammer unit was accomplished with a dual-wall sampling system. With the dual-wall system, once the sample depth has been reached, the inner rod with the dummy drive tip is removed, and the drive tip is replaced with a sampler. The sampler consists of a 6.67 cm (2.625 in.) OD × 4.76 cm (1.875 in.) ID outer sample barrel, which holds a 4.13 cm (1.625 in.) OD × 48.63 cm (18.75 in.) long inner sample barrel. The inner sample barrel houses three 3.18 cm (1.25 in.) OD × 15.24 cm (6 in.) long stainless steel sample liners. Once the sampler and inner rod have been lowered and seated into the outer drive rod, the two are simultaneously advanced far enough to ensure that the sampler is completely filled with material. Unless refusal is met, the sampler is typically driven 0.61 m (2 ft).

Prior to sampling, the sample liners, inner sample barrel, and sampling utensils were cleaned by 222-S Laboratory personnel using standard *Resource Conservation and Recovery Act of 1976* protocol cleaning methods in accordance with *ATL LO-080-156, Cleaning of Containers and Sample Collection Equipment*. Equipment used for push advance purposes (e.g., push rods, tips) was wiped down with a Simple Green® solution. This cleaning ensured that no cross contamination was introduced from the previous use of the equipment or from the manufacturing process.

RPP-RPT-56849, Rev. 0

Figure 1. Site Map for Stages I and II.

RPP-RPT-56849, Rev. 0

Samples were obtained and analyzed in accordance with WRPS Sample Authorization Forms, V13-001 and V13-002. Samples were analyzed for anions, pH, conductivity, radioisotopes, and several other analytes. Metals were analyzed using ICP mass spectrometry methods. Copies of the Sample Authorization and Chain of Custody forms are provided in Appendix F and sampling results are shown below.

2.4.3 Sampling Results

Table 1 shows the locations, intervals, sample numbers, and percent of sample recovered for samples taken during Stages I and II. Tables 2 and 3 show the sampling results for nitrate and Tc⁹⁹.

Based on the sampling results and descriptions of the soils recovered from the sampling efforts, the geophysical logs were expanded in the zones of interest for use in delineating the targets for testing and potential pore water extraction for Stage III. Figures 2 and 3 show the expanded logs with soil information included. These figures were utilized for precisely identifying the target zones for conducting borehole wall compaction reduction testing through performances of falling head testing and surging.

2.5 SPECIALIZED TESTING FOR STAGES I AND II

2.5.1 Falling Head Testing

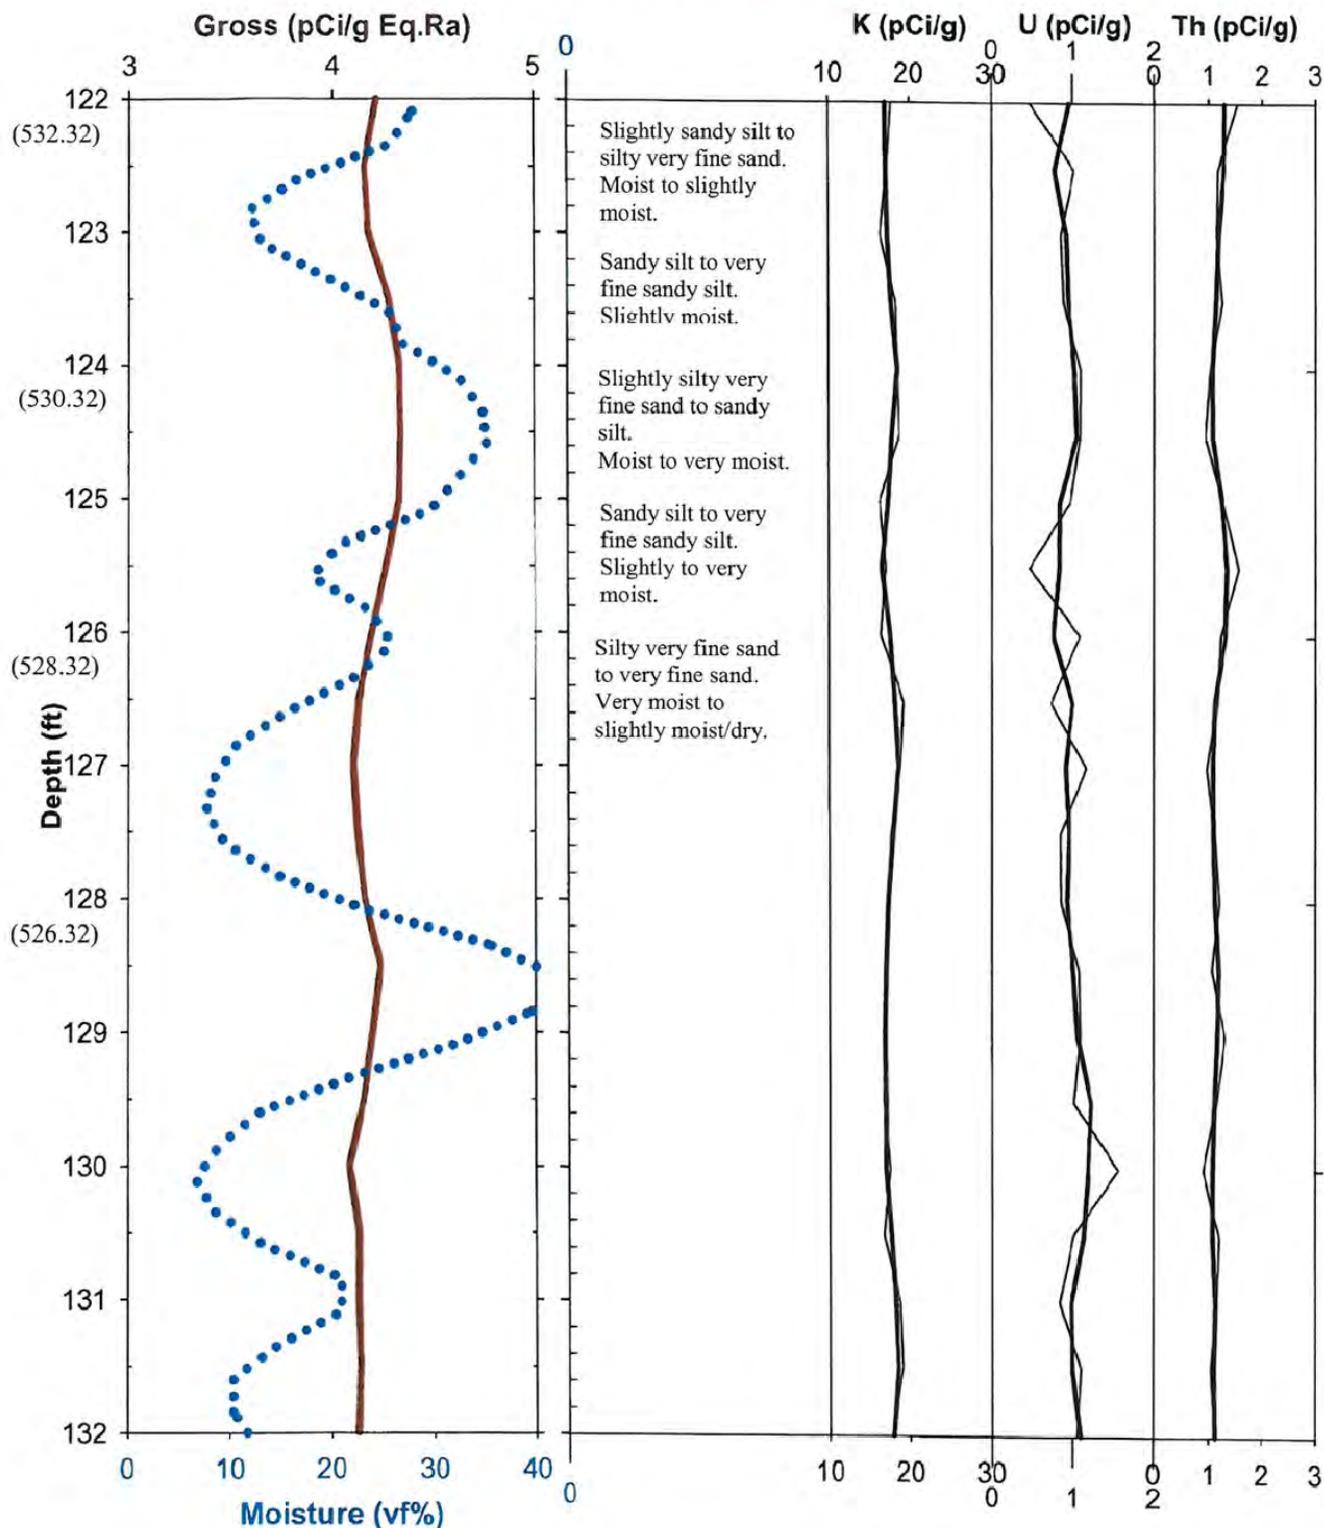

Material is compressed into the borehole wall as drill rods are pushed into the ground using the hydraulic push technique. This displaced material creates a compaction zone where approximately 0.75 cubic in. of material is compressed into each square inch of wall as the pipe is advanced. Falling head testing was performed as part of Stages I and II to evaluate the well development technique consisting of the introduction of water with subsequent surging and bailing to break down the compacted borehole wall. During project planning, it was speculated that this compaction skin (assumed to be essentially an impermeable barrier) would not allow, or would critically reduce the effectiveness of a vacuum for extracting water-bearing vapors from the formation. The falling head and surging activities were designed with two goals: 1) to provide the means to modify (i.e., break down) the compaction zone and 2) to collect data for comparison of the initial conditions and the conditions after application of the surging and bailing methodologies. Instructions for conducting the falling heads tests were prepared jointly by GSI Water Solutions Inc. (GSI) and EnergySolutions staff prior to field deployment.

Figure 3. Expanded Log for Zone of Interest C8761.

RPP-RPT-56849, Rev. 0

The falling head tests were conducted by centering a 2 ft long, 20 slot screen section in the zone of investigation. The screen and a sump were connected to the surface by a polyvinyl chloride (PVC) riser pipe. An In-Situ Inc.[®] Level Troll 700 pressure logging transducer positioned in the sump was connected to a computer at the surface. A measured volume of water was introduced into the borehole and allowed to infiltrate into the borehole wall and formation. The rate of decline of the height of water in the riser pipe (i.e., the falling head) was plotted on the computer. An onsite hydrologist observed the data plots and provided direction regarding length of time for data collection, whether or not to repeat the test, and actions taken at the conclusion of the individual tests.

Graphs generated by plotting the head height vs. time were utilized to calculate the borehole wall effective permeability, (K). This data was used to determine the net effect of the direct push methodology on formation permeability thus deriving a determination of initial effective permeability.

By viewing onsite plots of the falling head elevations, the onsite hydrologist could observe when the time vs. head height had reached “steady state” (i.e., the rate of change in the plotted curve was less than one). The test would be terminated and the pressure transducer would be removed from the well. If necessary, additional water was added to the well in order to assure that the zone of investigation (screen interval) had a sufficient fluid height to cover the screen. The volume of water added to the well was recorded on the daily work records. A slug rod/surge-block was inserted into the screen for surging the well. The screen zone was surged by the up and down movement of the slug rod/surge-block for up to 15 minutes and a measurement to determine the water level in the well was performed. The remaining water was removed from the well (purged) and a second falling head test was performed by placing a transducer, adding a measured volume of water, and tracking time vs. head height with the onsite computer graphics. The onsite hydrologist compared the generated test graphics (test 1 vs. test 2) and determined if additional water and surging was warranted, or if additional falling head tests needed to be conducted. These iterative steps of falling head testing and surging were repeated until comparison of the generated test graphics indicated that surging and bailing demonstrated no effective gain in the borehole wall permeability.

2.6 DATA AND INTERPRETATIONS

Falling head testing was planned for both C8759 and C8761. C8759 was the first well in which the placement of the test well screen and riser was attempted. After placement, based on the measurement of the total length of the screen and riser assembly compared to the length of casing present in the well, it was determined that the end cap of the sump and screen did not pass through the end of the 2.5 in. OD (1.75 in. ID) casing, as intended.

The clearance between the casing and the riser and screen was restricted, (the OD of the riser and screen was 1.66 in. and the ID of the casing was 1.75 in.) leaving a clearance of less than 1/20 in. (0.05 in.) on a side. The entire 2.5 in. casing string was removed to determine why the riser and screen would not pass through the casing shoe to total depth. On inspection, it was noted that when the disposable tip (which is held in place during driving with rivets through the casing into

RPP-RPT-56849, Rev. 0

the tip) was driven off to remove the tip before back-pulling the casing from total depth, jagged edges of the broken rivets were left protruding through the casing wall into the interior of the casing. There are four rivets points holding on the disposable tip. In this case, the total combined length of the broken rivets protruding into the interior of the casing was greater than the clearance allowed between the riser and screen assembly and the inner casing wall. Because the temporary screen could not be placed, no permeability testing was conducted in C8759 and the borehole was decommissioned.

To solve this issue, a cleaning shear was fabricated and was utilized to clean the broken rivets from the interior of C8761. This allowed the riser and screen to pass through the rivet section freely and falling head tests were conducted in this borehole.

GSI analyzed the data generated during the falling head tests. The primary data was collected during a series of five falling head tests done between March 12, 2013 and March 20, 2013 using pressure logging transducer installed in borehole C8761. Appendix G contains the GSI report on the falling head tests. The specific field activities performed during each test, data analysis, and hydrographs are provided.

Visual examination of the hydrographs indicates that during the first 100 plus seconds of each test, the water levels rose. This is interpreted to reflect the pouring of the 2 gallon test volume into the boring. For that reason, the report focused on the data collected after 100 seconds as this data was interpreted to provide the most information regarding the progress of development and the breaking down of the compaction zone within the borehole wall.

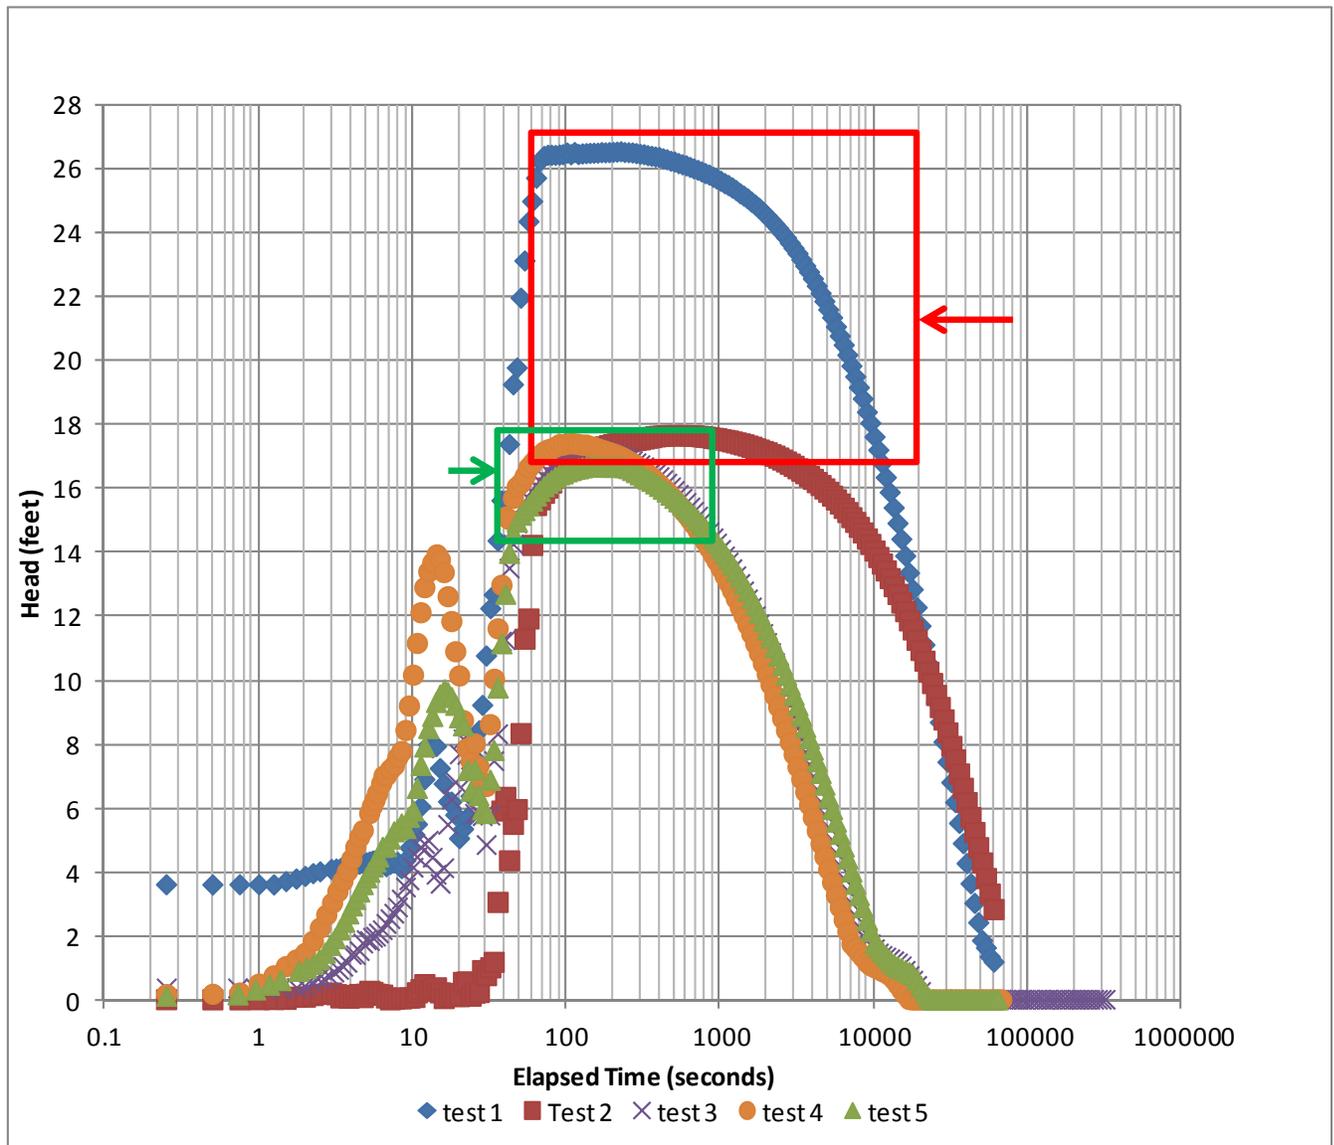

Figure 4 depicts the progressive change in borehole permeability as falling head testing, surging/purging and retesting progressed. Generally, in tests 1 and 2, the water levels rose and/or were static between 100 and 500 to 600 seconds into the test. Conversely, in tests 3, 4, and 5, the water levels began to decline between 100 and 200 seconds into each test. Later in the tests, both test 1 and 2 show that the boring took in excess of 60,000 seconds to drain while in tests 3, 4, and 5 the boring was largely drained by 10,000 to 20,000 seconds into the test. As indicated in Figure 4, there were no significant improvements in head decline rate or duration after the second round of surging and cleanout (between test 2 and 3). This indicates development/enhancement of wall permeability had improved as far as was readily achievable.

Based on the visual examination of the data, surging and purging (well development) was interpreted to have broken down the compaction zone within the borehole. The data suggests that the development work conducted between tests 4 and 5 yielded little to no additional improvements in the breakdown of the compaction zone, and that the boring was as developed as this technique could accomplish.

Additional comments and interpretations specific to each falling head test are given in the GSI report in Appendix G.

RPP-RPT-56849, Rev. 0

Figure 4. Falling Head Test Results for C8761.

2.7 CONCLUSIONS AND RECOMMENDATIONS

The well development process of purging and surging worked well to break down the compaction zone generated by the hydraulic hammer push technique. Based on the data, once development succeeds in breaking down the compaction zone, falling head tests will show a change from the trend seen in tests 1 and 2, (where water level was relatively static before it began to fall – critical portion of the curve in the red box in Figure 4) to that seen in tests 3, 4, and 5 where water level began falling from essentially the beginning of the test (see critical area enclosed in the green box in Figure 4).

RPP-RPT-56849, Rev. 0

For future well development activities, the following recommendations are made:

1. Once the borehole is ready for development, add a 2 gallon slug of water to it.
2. Leave this slug of water in the borehole for at least 12 hours. The purpose of this is to have water permeate the compaction zone to begin softening and degrading it in preparation for the subsequent surge and purge development.
3. Begin development activities using three to four surge and purge events. Each surge and purge will generally include:
 - a. Addition of 2 gallons of water to the boring.
 - b. Surging the boring for 30 minutes.
 - c. Purging that water from the boring.
 - d. Repeating steps a through c until such time as the purge water is visibly less turbid as compared to the initial purge.
4. When the purge water is visibly less turbid, conduct a falling head test.
 - a. Compare the graph from this test to the graph generated from the initial test to see if the slug of water stabilizes as it did in tests 1 and 2, or quickly begins to fall as it did in tests 3, 4, and 5.
5. If the slug shows the slow rise, stabilization, and slow fall seen in the first 30 minutes of tests 1 and 2, development of the compaction skin is interpreted to be incomplete, and steps 3 and 4, above, should be repeated.
6. If the slug shows the rapid fall seen in the first 30 minutes of tests 3, 4, and 5, development is interpreted to be having an effect on the compaction skin. In such a case, the final recommended steps are to:
 - a. Purge the well of the water from the slug.
 - b. Add a new clean slug.
 - c. Conduct one 30 minute surge operation followed by purging.
 - d. Add a new 2 gallon slug and conduct another falling head test.
 - e. If the slug is seen to be falling at rates similar to the previous falling head test, development can be interpreted to be complete.
 - f. If the slug is seen to be falling at a higher rate, then repeat bullets 6a through 6f.

RPP-RPT-56849, Rev. 0

3.0 STAGE III

3.1 SUMMARY OF ACTIVITIES

Field work to construct the wells for this stage started on June 14, 2013 and concluded on September 12, 2013. This included 59 field days. Approximately 131 hours (equivalent to approximately 14 days) were lost due to various reasons, including: lack of support, weather, and work package revisions. (See Appendix H for copies of the Drilling and Sampling Daily Work Records – Stage III).

PL-36472-OP-0002 provided the description of work for Stage III activities (see Appendix B). Direct push technology was used to place 2.625 in. OD pushes at four sites south of the 241-SX tank farm. The four boreholes were arranged in a 4 × 8 ft “box” to allow any of the four locations to be utilized as an extraction well or monitoring well and the eastern edge of the box was located within 5 ft of C8761. Using the geophysics from C8761, the target zones for the four wells were projected to be at 120 to 130 ft bgs in the individual locations.

The boreholes were driven to approximately 150 ft bgs. To reduce compaction in the anticipated zone of interest, the sampling string and sampler were utilized to advance the borehole through the 6 ft of the zone of interest. The recovered soil from the sampling string was disposed of in an onsite waste barrel. To reduce overall costs and improve efficiencies, logging was only performed from 90 ft bgs to total depth. Standard logging suites were used to collect gamma information and volumetric water content in each borehole. These logging suites consisted of a combination tool of LaBr/BGO for gross gamma and spectral gamma analysis, and a neutron-neutron detector.

After log data collection and processing, the data was reviewed to:

- Determine if the sediment type and bedding thickness were sufficient to meet extraction goals.
- Identify the borehole to be used for extraction and the three boreholes to be used for monitoring boreholes.
- Identify the precise depth for placement of the screen and packer assemblies.

A well screen and packer assembly was placed in the zone of interest in each borehole. Testing and well development was performed. Section 3.4 contains additional information on the placement of the well screen and packer assemblies, and Section 3.5 contains additional information on the testing performed.

After the testing and well development activities were completed, surface seals and connections to the surface extraction system were installed. EnergySolutions also provided ongoing field support to the project as the test continued. This support consisted of daily checks of the test equipment, sampling, and assistance as needed to modify or replace portions of the test equipment. This support work started on October 7, 2013 and included 46 field days, ending on

RPP-RPT-56849, Rev. 0

January 23, 2014. Results from the pore water extraction testing are not included with this report.

3.2 DIRECT PUSHING

Boreholes were driven using a hydraulic hammer system. Four boreholes were pushed using a 6.67 cm (2.625 in.) OD × 4.76 cm (1.875 in.) ID casing at predetermined locations to the specified depths, or refusal. When the borehole was in the zone of interest, as defined by the project, the standard sampling string was used to minimize the compaction of the borehole wall. The sampling string was used for three 2-ft sections (for a total of 6 ft) in each of the four direct push locations (C8823, C8824, C8825, and C8826).

3.3 GEOPHYSICAL LOGGING

Energy *Solutions* and Three Rivers Scientific conducted geophysical logging data collection and analytical services on the boreholes. A portable small diameter logging system was used to collect spectral gamma, gross gamma, and moisture data from the bottom of the borehole to 90 ft bgs. Calibration details, log data information, and data interpretation, as well as copies of the collected and processed data for the Stage III probe holes are provided in Appendix I. As stated above, only a portion of each of the four boreholes was logged (90 ft bgs to total depth). This interval was deemed sufficient to provide enough subsurface features to ensure accurate correlation to C8761, and provide detailed information relating to the target zones.

3.4 WELL SCREEN AND PACKER ASSEMBLIES

Extraction of moisture-bearing vapors from a given layer or geologic horizon requires a borehole construction method which allows negative pressure to be applied to the correct zone in the subsurface, and which seals the area above and below the target from the pressure effects. Additionally, a system to collect and pump the extracted water to the surface after removal from the formation is necessary. Included in the design requirements and operational planning was the goal that all of the subsurface equipment could be placed inside the working dimensions of the direct push slim hole tubing (1.875 in. ID).

During planning for the pore water extraction testing, WRPS contracted PNNL to conduct modeling and bench-scale testing of the soil moisture extraction concept, and to provide modeling information for use in selection of the zone for extraction, input on the design of the screen assemblies to place in the four wells, and parameters for operation of the extraction wells.

Multiple initial design and extraction concepts were proposed and evaluated prior to selection of the final design. The initial conceptual design plan consisted of a sealing system of inflatable packers on both sides of the screen interval, a sump, screen and riser, and a small-dimension pump for removal of the collected fluids.

RPP-RPT-56849, Rev. 0

The final configuration was a combination of non-deformable cement seals to seal the sump portion of the well and an inflatable packer for sealing the area above the screened extraction zone.

3.4.1 Design of Well Screen and Packer Assemblies and Construction Planning

Major factors of the extraction concept were:

- All materials and extraction devices had to pass freely through the drive tubing which had a 1.875 nominal ID.
- No extraction system was commercially available in the above dimensions. This restricted availability of items and materials that could be successfully placed into the tubing and caused difficult subsurface working conditions.
- The extraction zones required impermeable seals above and below the screen systems through which the vacuum would be applied to the formation.

The project team members expressed concerns about the initially proposed lower packer seal below the bottom of the screen. After discussion of various construction issues and fabrication restrictions, the recommended design was to replace the lower packer with a cement seal. Other design changes made included shortening the screen length to 1 ft, and reducing the screen slot size to ten slot from the 2-ft length, 20 slot screen utilized in Stages I and II testing.

The lack of space available in the annulus (area between the borehole wall and the screen/sump assembly) required that the material (cement) be placed into the bottom of the hole first and the sump portion of the assembly be displaced (pushed) into the cement. This was identified as a potential risk, as a very small variance in cement volumes could result in displacement of cement into the screen interval. To reduce the risk, numerous trial runs were conducted at the EnergySolutions shop area to establish precise cement volumes, mixing ratios, and to provide a reliable set of working instructions to guide activities in the field.

3.4.2 Installations of Construction Assemblies

Four sets of identical riser, packer, screen, and sump assemblies (hereafter called construction assemblies) were installed into the four boreholes. After installation, falling head testing was conducted in accordance with the conclusions and recommendations from testing conducted during Stages I and II (Section 2.7). This testing revealed complications to the installations of three of the four wells. As the sump was pushed into the cement, the cement rose in the annulus and covered portions of the screen intervals.

During construction, no material was detected during measurements inside the sump. Measurements taken several days after the placement of the construction assemblies were the first indication that materials had entered through the screens. Because no measurements were possible in the annulus, the amount of screen interval compromised is not known. In well C8823, approximately 0.8 ft of cement was measured in the sump and the conclusion is that some amount of cement rose above the bottom of the open screen interval and entered the well. In well C8824, no material was noted inside the well and the assumption is that no cement rose above the bottom of the screen interval. For well C8825, the cement material inside the casing

RPP-RPT-56849, Rev. 0

was measured to be within 0.2 ft of the top of the screen. This measurement demonstrates that the sump and 80% of the screen are full of cement. In well C8826, approximately 1 ft of cement was noted inside the sump the day after the placement of the construction assembly. See Figures 5 through 8 for as-built drawings depicting the construction details of each well (C8823 through C8826).

It is assumed that the above noted complications indicate that the cement infiltration through the screens did not occur immediately. Before placement of the cement and screen assemblies/risers, each well was measured to ensure that the borehole was open and ready for the installation. A measured amount of cement was then placed into the bottom of the well by use of a dump bailer. The screen assemblies and risers were then placed into the well bore and displaced (pushed) into the cement. Measurements were taken down the borehole after the installation of the screen assemblies and risers. No material was detected inside the sump or screen after the placement of the construction assemblies in any of the four wells. No materials were detected inside the sump until the wells were re-measured several days later at the initiation of well development activities. The conclusion is that after placement of the cement, and before, or as the construction assembly was placed into the cement, formation materials caved into the borehole and mixed with the cement, causing an increase in the cement volumes. This increase in cement volume was sufficient to cause it to rise into the screen interval in three of the four wells. It is also surmised that the addition of the sand/silt formation material into the cement caused the cement fluid viscosity to rise sufficiently to not allow immediate ingress through the well screens which is why the infiltrations were not identified at the time of placement.

3.5 FALLING HEAD TEST DATA AND INTERPRETATION

Following the placement of the screen assembly, the well development process of purging and surging was performed as described in Section 2.7.

Wells depths were measured and an In-Situ Inc.® Level Troll 700 transducer was utilized to monitor water levels within the wells during testing. The testing sequence data was collected and GSI provided interpretations of the data. Plots of the falling head data as well as an interpretation of the data are provided in Appendix J. A discussion on the well development and falling head testing on each borehole is provided below.

3.5.1 C8826

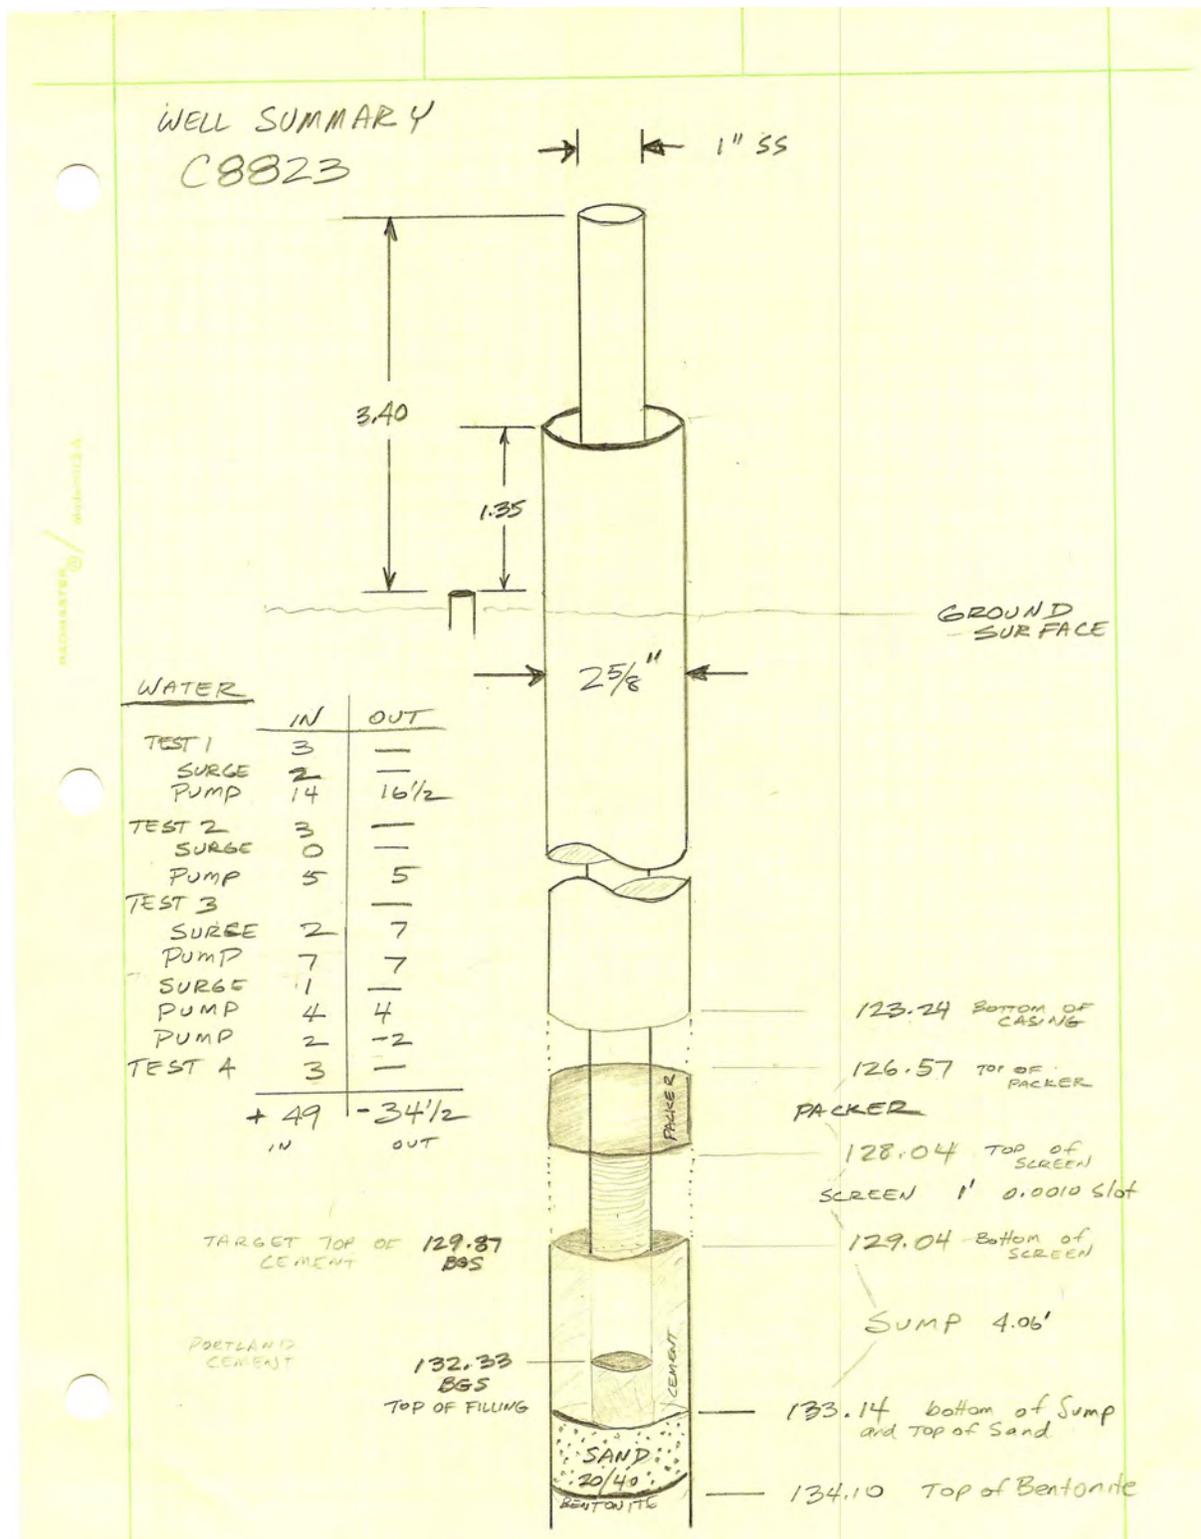

Well C8826 was the first of the four Stage III wells in which development efforts were conducted. In total, eleven individual falling head tests and surge/purge sequences were performed in well C8826. The repetition of testing and purging was the result of the inconclusive results and data plots collected. Figure 9 shows the normalized data plot of the multiple tests performed during the attempt to break down the sidewall compaction zone.

The falling head and purging steps were repeated with minor modifications to the process and to the equipment in an effort to effect change and derive data plots similar to those in Figure 4 (from the initial falling head tests done in C8761). Throughout all of the repeated attempts to

RPP-RPT-56849, Rev. 0

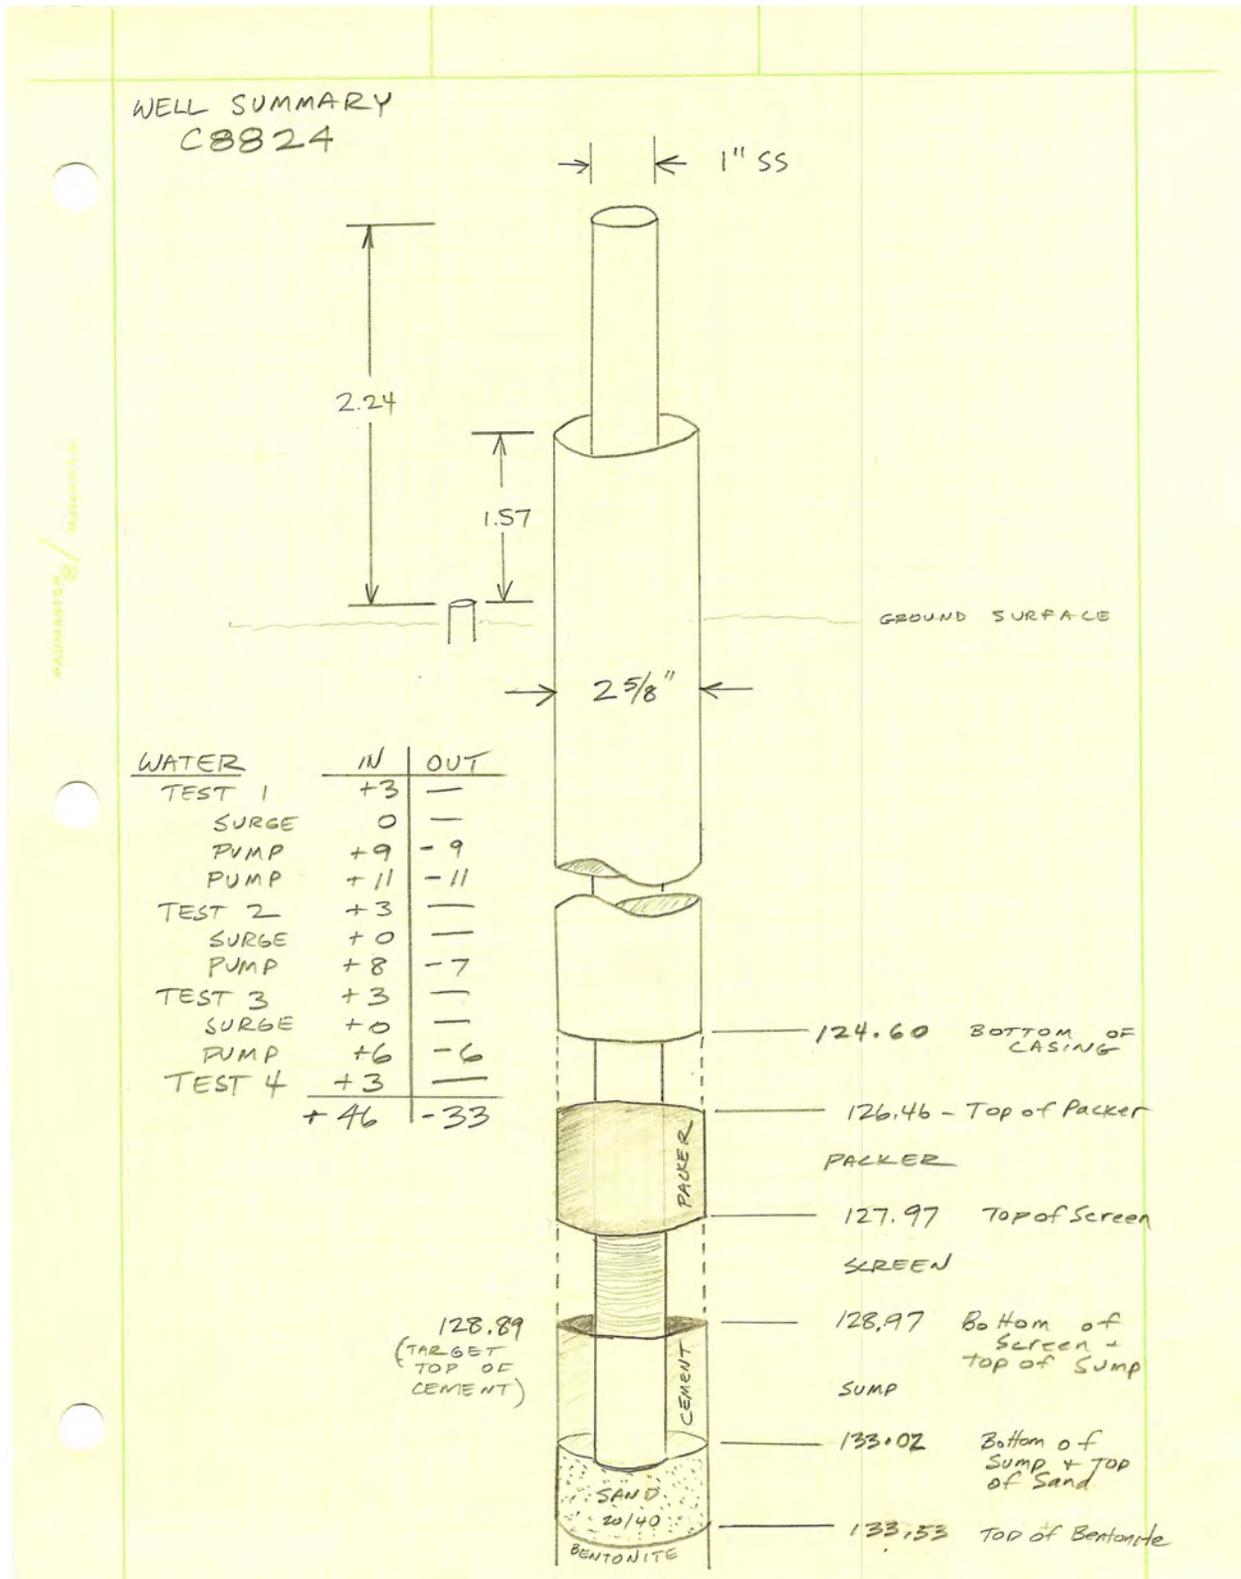

increase the effective borehole wall permeability, little or no improvements were observed. In fact, the initial test and test 4 had the best effective infiltration rates.

Figure 5. As-Built Drawing for C8823.

Figure 7. As-Built Drawing for C8825.

RPP-RPT-56849, Rev. 0

Figure 8. As-Built Drawing for C8826.

RPP-RPT-56849, Rev. 0

None of the curves depicted in Figure 9 show the improvement or curve profile shown for tests 3 through 5 in Figure 4.

3.5.2 C8825

Figure 10 shows the normalized well responses from the four falling head infiltration and purge cycles performed on C8825. None of the curves match the pattern expected or meet the development goal from the testing done in C8761. Test number two had the fastest rate of decline and the remaining three have the long, nearly flat, time span with a very slow rate of decline between 100 and 1000 seconds into the test duration. These responses demonstrate that the surge and purge (bailing of fluids and materials) from the sump portion of the well did not producing results similar to the actions performed in C8761.

3.5.3 C8824

Figure 11 depicts the normalized responses from four falling head and surging/purging cycles in well C8824. No significant improvements were achieved from the process. Test number one had the fastest initial decline in head and the subsequent three tests had prolonged delays in the head decline in the 100-1000 second time frame.

3.5.4 C8823

Figure 12, the normalized graph of four falling head tests conducted in well C8823, clearly shows that all three tests had no affect on borehole permeability. It demonstrates that the surging produced no reduction in the borehole wall compaction and most likely produced plugging of the screen and/or the borehole wall with fines.

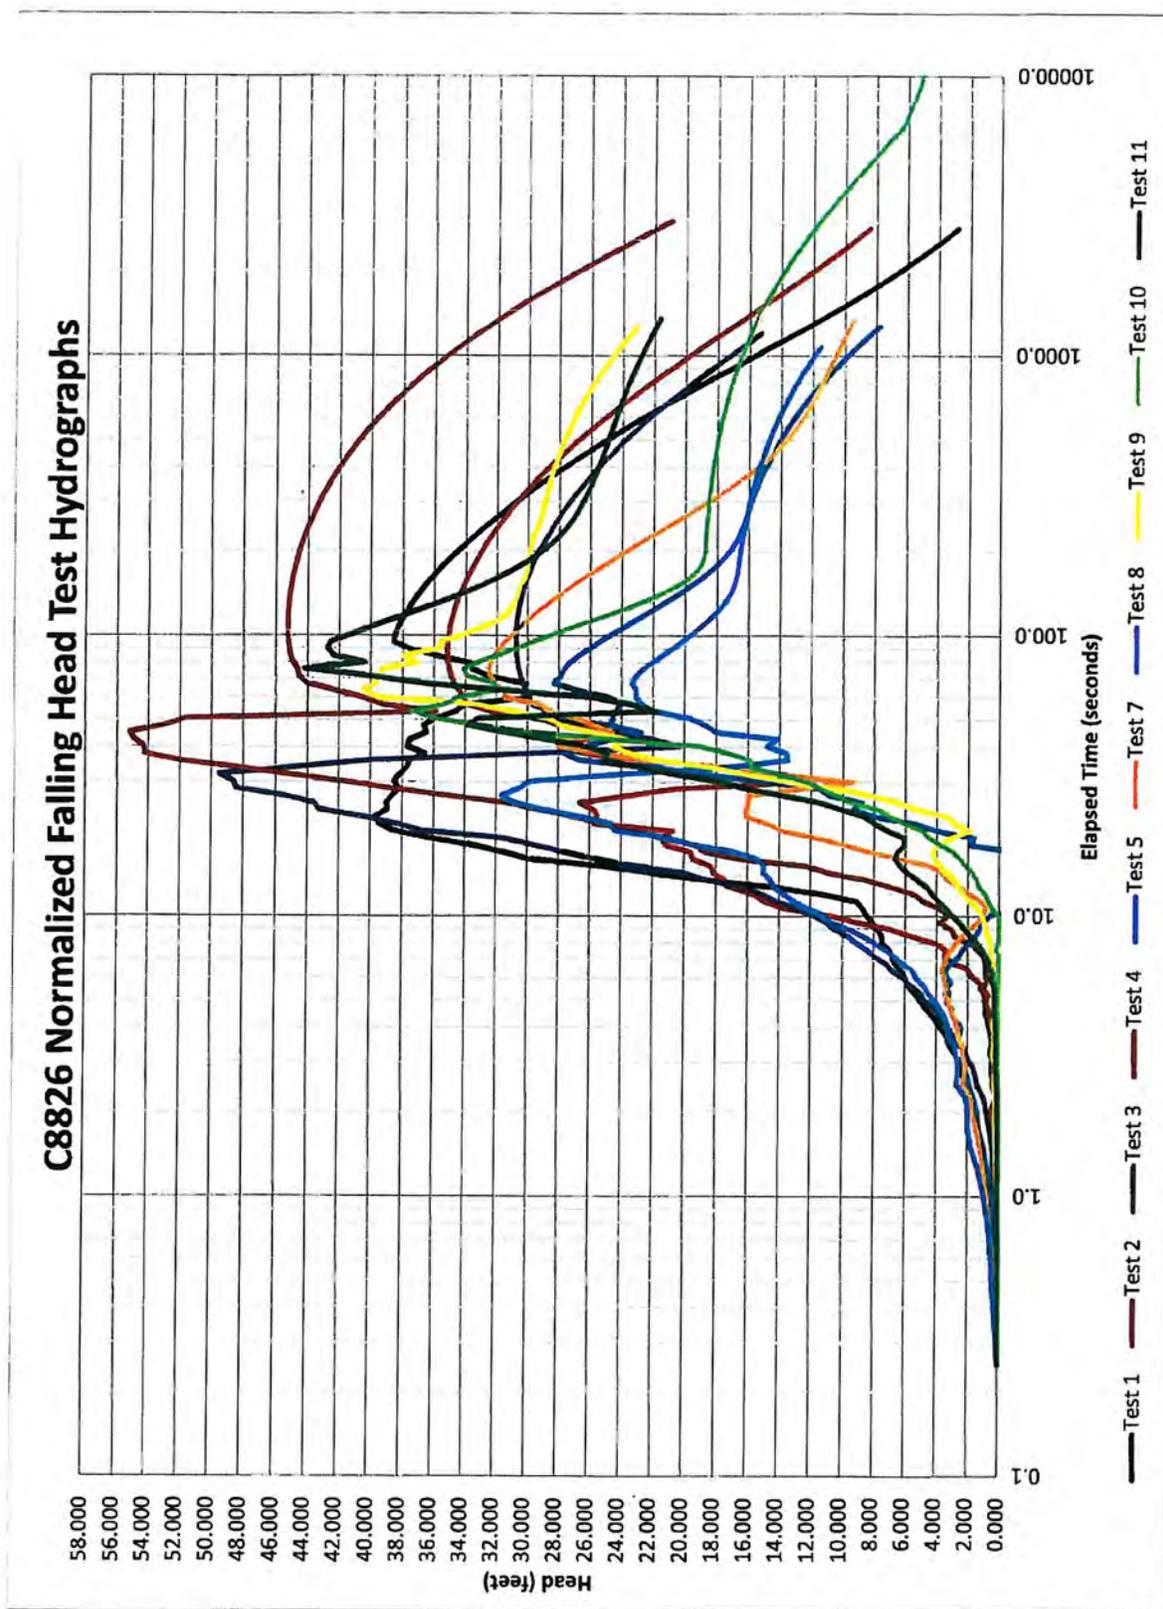

3.6 CONCLUSIONS AND RECOMMENDATIONS

During Stage III, in all four boreholes, the well development process had no effect on the compaction in the borehole wall or increasing the effective permeability. In fact, the permeability appeared to go down as the testing and purging progressed. There are several issues that may have contributed to these results:

- The wells were constructed with 1 in. nominal ID risers with 1.33 in. ID screens and sumps. The surge block/slug rod had to fit through the 1 in. ID riser, but had excess room in the 1.33 in. ID screen and sump. This reduced the compression wave in the fluid as the surge block was moved up and down in the screen section, reducing the effectiveness of the surging process.
- The screen section was changed from the 2 ft/20 slot tested in C8761 (Stages I and II) to 1 ft/ten slot for the four extraction wells in Stage III. The reduction in length was intended to keep the extraction vacuum centered within the target zone to reduce the chances of breakthrough and channeling of the vapor pathway into the well from the adjacent, less saturated sediments. The slot size reduction was based on concerns that the larger sized, 20 slot openings would allow excess sediments into the screen and sump, and damage or plug the water extraction pumping system.

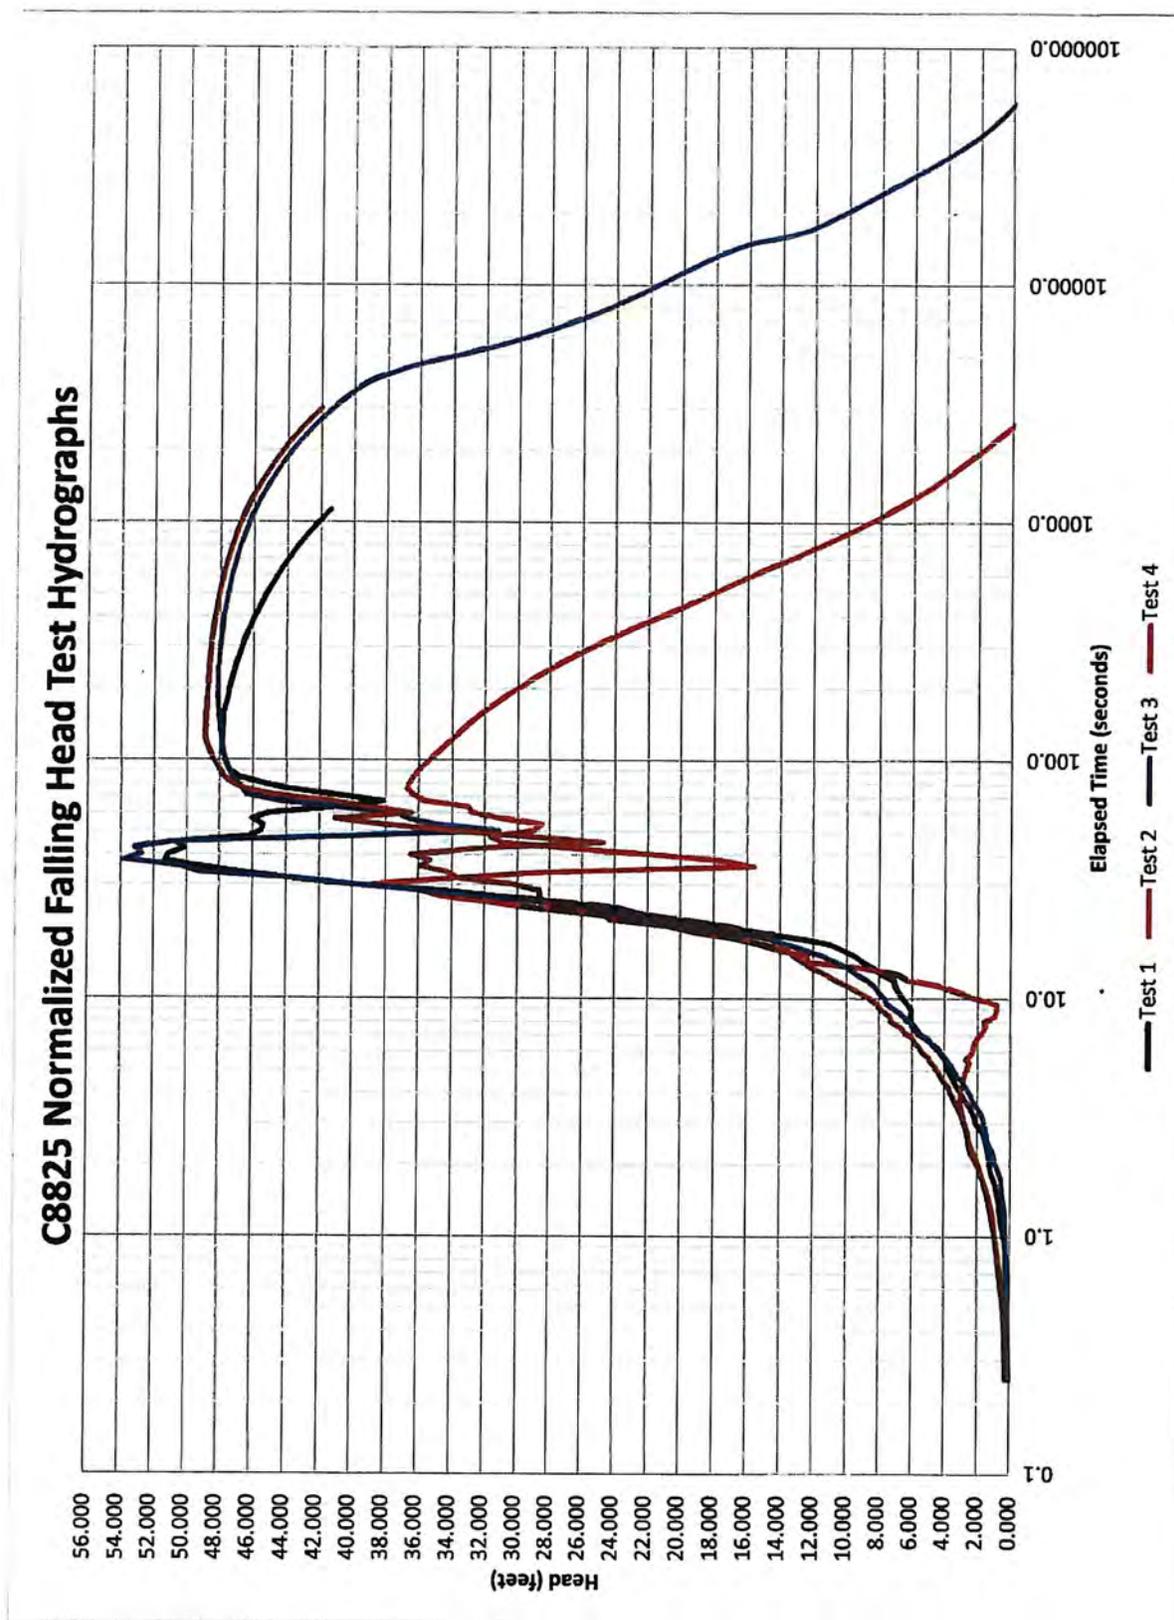

RPP-RPT-56849, Rev. 0

Figure 12. Hydrograph of C8823 Falling Head Testing.

RPP-RPT-56849, Rev. 0

- The decrease in slot size contributed to the reduction of surging energies for development of the borehole wall.
- Observations during the bailing process indicate little or no material (sand or silt) was removed from the well (i.e., no materials entered the well through the well screens). This can be attributed to: 1) the reduced slot size, or 2) the problems with the construction where significant portions of the screen interval were subjected to infiltration by cement during the placement of the construction assembly into the cement at the bottom of the wells.
- During operation of the vacuum system, one or more of the packer systems failed to maintain pressure. These failures could have been manufacturing flaws, as the systems were custom-made to fit in the extremely tight dimensions of the 1.875 in. ID of the well, but the precise cause and nature of these failures is not known.

To overcome the issues noted above, several changes should be made prior to any additional testing:

- The overall working dimensions of the well need to be enlarged. A larger borehole size would allow the construction assembly to be cemented into place using a tremie pipe to place cement down the hole around the assembly. This would eliminate the problems caused by pushing the construction assembly into cement at the bottom of the hole.
- The increase in size should be accompanied with a uniform ID/OD for the construction assembly (see the first bullet in the discussion of issues, above) to maximize surging pressures from the well development process. The screen system should be returned to the 20 slot opening size to ensure that surging energies are more efficiently applied to the borehole wall. Both of these changes would increase the breakdown of the compaction zone and improve borehole wall permeability.
- Increasing the working dimensions for well placement would also allow the use of non-deformable seals above the screen after well development. This would eliminate the mechanical failure issue with the packer system.

4.0 BOREHOLE DECOMMISSIONING

Decommissioning of the boreholes from Stages I and II were conducted in accordance with the *Washington Administrative Code (WAC) 173-160* requirements. While decommissioning the boreholes, the tubing was back-pulled while granular bentonite was simultaneously added to the tubing until it reached the surface. Resistivity probes were installed in one borehole, C8761. A protective steel casing was cemented in place approximately 30.48 cm (12 in.) deep at the surface to protect the protruding probe wiring. The State of Washington, Department of Ecology (Ecology) documentation is provided in Appendix K.

RPP-RPT-56849, Rev. 0

Stage III boreholes have not yet been decommissioned as they are being used for the pore water extraction testing. Table 4 shows the logged and sample boreholes, coordinates, pushed depths, and resistivity probe placement depths, as applicable.

5.0 GLOBAL POSITIONING SATELLITE SURVEYING

With the use of a Trimble® 5800 Global Positioning Satellite Survey system, or equivalent equipment, the original locations of the exploratory boreholes were identified using paint and stakes. Once the task was completed and the boreholes were decommissioned, each exploratory and sample borehole was recorded for accuracy. These recorded coordinates were placed on a map showing their locations in direct relation to the underground storage tanks in the vicinity. The coordinates, elevation, and a map showing completed push locations/boreholes are provided in Appendix L.

6.0 ENVIRONMENTAL, SAFETY AND HEALTH

During the SX Tank Farm activities, EnergySolutions Operations Safety personnel performed job site surveillance for safety and health compliance. The results of a surveillance performed by EnergySolutions are provided in Appendix M. The work scope conducted under the subject Statement of Work was completed with no lost time, reportable *Occupational Safety and Health Act of 1970* injuries, or first aid cases, and there were no incidences of equipment or personnel radiological contamination.

Rev. 0**DESCRIPTION OF WORK: SX PORE WATER EXTRACTION
STAGE I****1.0 INTRODUCTION AND BACKGROUND****1.1 GENERAL DESCRIPTION**

There are 177 large, underground tanks located at the Hanford Site, 149 of them are single-shelled. These tanks and their associated facilities are grouped into 12 "tank farms." The tanks were used for storage of some of the most dangerous and hazardous waste produced during the processing of irradiated fuel to obtain plutonium. Tank farms were located downhill from chemical separations plants so that the wastes would gravity-flow to the tanks. Six single-shell tank (SST) farms (241-S, 241-SX, 241-T, 241-TX, 241-TY, and 241-U) are located in the 200 West Area of the Hanford Site. This Description of Work (DOW) focuses on the SX tank farm and an investigation related to extraction of potentially contaminated pore-water from under and adjacent to the SX tank farm. This DOW provides the work instructions for conducting characterization and sampling efforts for Stage I of the SX Pore Water Extraction as listed in RPP-PLAN-53808, Rev. 0 or latest revision. The scope of work includes: providing equipment and personnel to conduct direct push activities; supporting soil sample collection by Washington River Protection Solutions, LLC (WRPS) sampling personnel; providing safety oversight; providing geophysical logging services; performing falling head tests and borehole wall manipulation activities in selected zones of the exploration boreholes; attending meetings and planning sessions; and providing a written report documenting field activities and data collection at the conclusion of the scope of work. This work is being conducted at the direction of WRPS Closure and Corrective Measures group.

1.2 BACKGROUND

The U.S. Department of Energy (DOE) assigned the River Protection Project (RPP) Single-Shell Tank Program the tasks of transferring waste from the SST to double-shell tanks, and developing and implementing a strategy to retrieve SST waste and miscellaneous underground storage tank waste. The WRPS Closure and Corrective Measures group was given responsibility for collecting and providing subsurface data from the SST farm facilities. This contributes to preparation for the eventual retrieval of the tank waste. The intent of the SST Waste Management Area (WMA) characterization program is to collect and analyze samples to provide an understanding of the distribution and movement of contaminants in the vadose zone under and adjacent to the tank farms. These SST farms are designated as Radiological Buffer Areas or Contamination Areas.

The SX tank farm is believed to have been associated with tank waste losses to the soil column as a result of overfilling, leaks from ancillary equipment, and/or leaks from the tanks themselves. Detailed estimates of soil waste inventories have been prepared for this tank farm and are

RPP-RPT-56849, Rev. 0

Rev. 0

documented in various reports identified in RPP-PLAN-53808, *200 West Area Tank Farms Interim Measures Preliminary Investigation Work Plan*.

The initial field testing of soil desiccation/contaminant removal technology called out in RPP-PLAN-53808 includes testing referred to as Stage I Pore Water Extraction. The purpose of the Pore Water Extraction testing is to determine if the technology has potential to remediate identified contamination. Stage I will characterize the study area for selection of a test site and provide technical information for performing a proof-of-principle test of soil desiccation/contaminant removal using direct push equipment.

Results of previous soil investigations at SX tank farm indicate the presence of contamination within the vadose zone. The most effective way to mitigate risk associated with this contamination is through restriction of groundwater recharge using interim surface barriers or removing contaminants in the vadose. RPP-7884, *Field Investigation Report for Waste Management Area S-SX*, indicates future risk is best mitigated by reducing both the subsurface moisture content and the soil contaminant inventory. Previous work completed at T and TY tank farms resulted in the installation of interim surface barriers to reduce soil moisture. The work planned in this document evaluates the potential to reduce the subsurface soil moisture and contaminant inventory through pore-water and vapor extraction.

1.3 TANK FARM BACKGROUND

The SX tank farm was constructed between 1953 and 1954 and consists of 15 SSTs. The 241-SX tanks are arranged in rows of three tanks each, downhill from the chemical separations plants, each tank slightly at a slightly lower elevation than its neighbor so that the wastes gravity-flow into the tanks. Each of the 241-SX tanks has a nominal 1 million-gal storage capacity, and consists of a carbon steel liner inside a reinforced concrete shell. The steel tank liner covers the 75-ft inner diameter tank bottom and sidewalls to a height of approximately 32 ft as measured from the tank center. The tank bottom is dish-shaped and slopes approximately 3.3% from the sidewall to the tank center (i.e., 14.875-in. elevation drop over 37.5-ft radius).

Ten of the tanks in the SX tank farm have laterals (cased borings) installed below the tank bottoms as part of the leak detection system. In addition to laterals, vadose zone monitoring wells (drywells) are installed throughout the tank farm for leak detection.

1.4 PHYSICAL SETTING

The SST tank farms were constructed in excavations into the near-surface sediments that overlie the Columbia River Basalt Group. The Columbia River Basalt forms the basement bedrock. There are approximately 169 to 179 m (555 to 590 ft) of continental sediments that overlie the basalt in WMA S-SX. From oldest to youngest, these deposits include the following.

- Columbia River Basalt Group
- Ringold Formation

RPP-RPT-56849, Rev. 0

GG-NW-DOW-001
Rev. 0

- Cold Creek unit – lower carbonate rich sequence (CCU_l)
- Cold Creek unit – upper silt and sand sequence (CCU_u)
- Hanford formation – lower fine sand and silt sequence (H2 subunit)
- Hanford formation – middle coarse sand and gravel sequence, upper fine sand and top gravelly sand sequence (H1 subunit)
- Backfill

The general characteristics of these units are described in more detail in RPP-23748, *Geology, Hydrogeology, Geochemistry, and Mineralogy Data Package for the Single-Shell Tank Waste Management Areas at the Hanford Site*. All of the formations, except for the surface of the Hanford formation have a general tendency to dip west to southwest toward the axis of the Cold Creek unit. The SSTs at WMA S-SX were emplaced within the Hanford formation sediments of an upper sand-dominated (H1) subunit, and may locally intercept the upper portions of a middle gravel-dominated Hanford (H1) unit. The vadose zone beneath WMA S-SX is as much as 65 meters thick (213 ft) and consists of the Hanford formation, the Cold Creek unit, and the upper part of the Ringold Formation. Both the water table and the unconfined aquifer reside entirely within the Ringold Formation.

Sediments in the vadose zone vary from open-framework gravels of the gravel-dominated facies and interbedded sand and silt of the silt-dominated facies of the Hanford formation to calcium carbonate-rich deposits of the Cold Creek unit and cemented gravels of the Ringold Formation. These sediments are characterized by numerous lateral discontinuities, such as pinch outs, erosion truncations, and irregular flow patterns. If elastic dikes are present, they may enhance vertical flow patterns. Therefore, there are numerous possible avenues for contamination to migrate through the vadose zone (HNF-4936, *Subsurface Physical Conditions Description of the S-SX Waste Management Area*).

2.0 WORK SCOPE

For the Stage I activities EnergySolutions Government Group, Northwest Operations (EnergySolutions) will utilize a direct push technology to place exploratory and sampling pushes at three sites south of the 241-SX tank farm. At these sites the exploratory holes will be driven to refusal, which is anticipated to occur at 120 to 130 ft below ground surface (bgs). These exploration holes will then be utilized for collection of remote sensing geophysical log data. Gamma information, volumetric water content and soil formation temperature data will be collected with standard logging suites. These logging suites consist of a combination tool of lanthanum bromide and bismuth germinate oxide (LaBr/BGO) for gross gamma and spectral gamma analysis, a neutron-neutron detector, and an infrared casing temperature device.

The log data will be utilized to select intervals for sampling in separate pushes located 2-3 ft from the exploration locations. Two zones will be selected from each exploration borehole for investigation. The samples will be analyzed on a "quick-turnaround" basis for moisture content, nitrate and, technetium. After sampling has been completed and the sampling boreholes have been decommissioned, several testing activities will be undertaken in the exploration boreholes.

RPP-RPT-56849, Rev. 0

GG-NW-DOW-001
Rev. 0

The casing will be withdrawn to provide open hole access to the zone sampled in the sampling borehole. A temporary screen and riser pipe will be placed in the zone of interest and instrumented with a piezometer. A "falling head test" designed for implementation in the vadose zone will be conducted by placement of 2-5 gallons of water per test. At least one test and possibly several tests will be performed. In addition to recording the falling head test data, the zone being tested will be surged in an attempt to modify or breakdown the compaction zone created along the borehole wall by the direct push methodology.

2.1 METHOD FOR BOREHOLE PLACEMENT

The method selected to outline the vertical and horizontal extent of contamination is a hydraulic hammer-driven push system on a tractor or track mounted type carrier. For this application, the locations for investigation (exploration) are selected through an iterative process as outlined in Section 3.0, "Push Locations." Data from the moisture and gamma logs collected from the exploration borehole will be used to determine sampling locations in the adjacent sampling push location. Approximately six samples will be collected in the three adjacent sampling push locations.

2.2 EXPLORATORY BOREHOLE

The exploratory activities are initiated by placement of a single tubing string that is 6.4 cm (2.5-in.) outside diameter (OD) x 4.45 cm (1.75-in.) inside diameter (ID) (e.g., the exploratory push). This tubing is advanced to the target depth or refusal. Geophysical logging with bismuth germinate oxide gamma and neutron-neutron moisture instrumentation is conducted. The logging data is reviewed by the WRPS Closure and Corrective Measures and EnergySolutions technical personnel to determine target sample collection points. After testing, the exploratory borehole will be decommissioned per applicable *Washington Administrative Code (WAC)* 173-160, "Minimum Standards for Construction and Maintenance of Wells," requirements (e.g., filled with bentonite or bentonite/cement grout as required) as the push tubing is extracted.

2.3 SAMPLE BOREHOLE

Sampling is conducted with outer push tubing that is 6.67 cm (2.625-in.) OD x 4.76 cm (1.875-in.) ID and inner tubing that is 3.81 cm (1.5-in.) OD x 2.54 cm (1.0-in.) ID. The dual wall system with a "dummy" tip is advanced to the predetermined sample depth. When the sampling depth is achieved, the entire tubing string (inner and outer casing) is back-pulled 0.06 m (approximately 2 in.) to 0.12 m (approximately 5 in.) to relieve pressure from the drive shoe and tip. The removable tip is removed by extracting the inner rods. When the inner string of tubing has been removed, a sampler is attached to the inner string and returned to the bottom of the outer casing/push tubing and positioned against the inner receiver face of the drive shoe. The inner and outer tubing strings are "locked" together by use of a proprietary method, and the entire assembly is advanced through the targeted sample interval.

RPP-RPT-56849, Rev. 0

GG-NW-DOW-001
Rev. 0

The sampler body holds three stainless steel liners that are 3.17 cm (1.25-in.) OD x 2.7 cm (1.08-in.) ID. After the sampler is advanced approximately 0.6 m (2 ft), the inner string is released and retrieved to surface. The liners are removed from the sampler body and surveyed. Trained sample-handling technicians document recovery, sample condition, and volume recovery percent; then the samples are packaged and transported to the selected laboratory for analysis. The samples will be analyzed on a "quick-turnaround" basis for moisture content, nitrate, and technetium. The "dummy" tip is reattached to the inner string and returned to the bottom and placed in the casing shoe, and the entire assembly is then advanced to the next designated sample depth. This process is repeated until all requested samples have been collected or the tubing meets refusal.

Upon completion of the final sample extraction, or upon meeting refusal, the dummy tip or sampler is removed and the borehole is decommissioned per WAC 173-160 requirements, as described in Section 3.6, "Exploratory and Sampling Hole Decommissioning."

2.4 PLACEMENT OF BOREHOLES

Sites selected for the push locations are south of the SX tank farm fence line and are a portion of proof-of-principle testing to obtain moisture information and soil chemistry about three prospective test locations with characteristics similar to those anticipated beneath SX tank farm. The general location for the three prospective test locations, in relation to 200 West Area and the Hanford Site, is shown in Figure 2-1. Ground penetrating radar (GPR) and electrical ground scans will be performed before boreholes are pushed, to identify sub-surface infrastructure and support citing of the test boreholes. The combination of subsurface infrastructure and surface accessibility will be used to determine the exact location of each borehole. The push location will be staked by use of Global Positioning Satellite equipment and verified by a licensed land surveyor.

Table 2-1 contains the proposed co-ordinates and borehole numbers associated with each borehole location. Figure 2-2 shows a close-up location of the boreholes showing the southern fence line of SX tank farm.

Table 2-1. Coordinates of Boreholes for Stage I.

Site #	Borehole #	Use	Northing	Easting
#1	C8757	Exploration	134133	566773
	C8758	Sampling		
#2	C8759	Exploration	134127.9	566814.9

Rev. 0

2.4.1 Push Location Documentation

These locations were selected through an iterative process using GPR data and review of as-built infrastructure drawings. The infrastructure interferences were reviewed from available drawings and site walk downs and this data was utilized for review of the GPR data. Based on this iterative process, three proposed areas were identified with an alternate for push site locations.

The final coordinates of the selected site were then plotted with computer-aided drafting. The push locations are documented above (see Table 2-1). In addition to the coordinate position of each push location, the push depth, geophysical log data, and other pertinent information derived during the activity (e.g., depth of contamination as identified from geophysical log interpretation and degree of contamination observed on push rods during extraction) is included in the Field Activity Reports and State of Washington, Department of Ecology-required documentation.

2.4.2 Push Location Tables And Numbering

All exploratory and sampling push location activities are tracked and documented on Field Activity Reports by referencing the Well identification (Well ID) number as provided in Table 2-1 or assigned during progress of the work. If sample collection is attempted, a unique Well ID number will be used to track the push location on the Field Activity Report, and the sample will be identified with that Well ID number on the sample label and the shipping documentation. The Well ID for a sample borehole is one number greater than the corresponding exploration borehole (e.g., if a zone of interest is identified at exploration Well ID C8757, the Well ID of the subsequent sampling push is C8758). The unique Well ID number for both the exploratory push and sampling push locations have been assigned and listed for use during the Stage I SX Pore Water Extraction Test by the Hanford Site Well Coordinator.

3.0 WORK TASKS

3.1 SITE SETUP

The push equipment will be mobilized and a controlled work area set up surrounding the preselected and marked location (see Figure 2-2 above). A radiological pre-survey of the tractor and equipment will be conducted (per WRPS procedure) prior to moving the equipment into the work zone. As noted above, GPR scans and as-built drawing reviews and comparisons have been completed to properly select the push location. The push equipment consists of a tractor-mounted mobile unit with a hydraulically-powered hammer and mast system. Support equipment to be used during field activities will be mobilized into the work area as needed. A forklift will transport needed support equipment to and from the push locations. Tank farm personnel will provide support, as necessary, for guiding the equipment onto location and for subsequent movement of the equipment to other locations.

WRPS Radiological Control Technicians and Nuclear Chemical Operators will be onsite to support work during activities that create potential personnel exposure. Contamination control

RPP-RPT-56849, Rev. 0

GG-NW-DOW-001
Rev. 0

measures will consist of laying spill protection material beneath the equipment (when required). Spill protection consists of felt and plastic sheeting placed on and around the direct push unit when necessary and prudent. Control of the work area and control of potential contamination are aided by restricting site entries by unnecessary personnel. WRPS Health Physics personnel will provide direction and support to ensure radiological protection is maintained for all personnel associated with the work.

3.2 PRECAUTIONARY MEASURES

During advancement of the boreholes, casing (push rods) will be driven into the subsurface by use of the hydraulic hammer impact system. The push locations have been positioned to avoid impacting known/mapped structures. Careful observation of the push advance rates and resistance will be observed to preclude damage to any tank farm infrastructures should the as-built drawings be erroneous. If rod advance indicates that obstructions are present, push advance will stop, the direct push equipment and work area will be placed in a safe condition and the Closure and Corrective Measures Technical Lead or his designee, and the WRPS field work supervisor will be notified. If during push operations, a borehole is deemed to be "at refusal" as defined by trained operators of the direct push equipment (refusal is defined as a minimum of one inch of advance per minute of impact operations), the length of tubing driven will be noted in the Field Activity Report and the next sequential task as defined in Section 2.2 or 2.3 (depending on whether the borehole is an exploratory or a sampling borehole), will be performed.

All activities using the hammer unit will conform to the manufacturer's operating manual and applicable procedures and work package instructions that relate to the specific phase of work. As the push rods are extracted from the exploratory and sampling holes, the onsite Health Physics Technician will monitor for radiological contamination. WRPS tank farm-qualified Nuclear Chemical Operators will perform any decontamination required. The sealing requirements for decommissioning of the boreholes are defined in the appropriate sections of WAC 173-160.

3.3 GEOPHYSICAL LOGGING

At refusal or target total depth of the exploratory investigations, *EnergySolutions* will conduct logging operations to gather geophysical information. These geophysical investigations will be conducted in conformance with *EnergySolutions* procedure GG-NW-FA-PR-001, *Geophysical Logging* and the *EnergySolutions* document ESTP-QA-PN-001, *Engineered Systems and Technology Projects – Quality Assurance Program Plan*. Logging parameters may be changed and/or log suites may be added or deleted based on the technical needs of the project, as determined by the WRPS Closure and Corrective Measures Technical Lead. The following logging suites are planned.

RPP-RPT-56849, Rev. 0

GG-NW-DOW-001

Rev. 0

1. Lanthanum Bromide/ Bismuth germanium oxide (LaBr/BGO) @ 100 seconds/0.5 ft
2. Additional logging with the "Red" and/or "Green" Geiger/Muller equipment, if necessary, based on observed results
3. Neutron-neutron detector with a client (WRPS)-provided Americium Beryllium source for moisture logging @ 15 seconds/0.25 ft
4. Infrared casing temperature detection (collected simultaneously to the LaBr /BGO detection).

Logging data will be collected from the surface to the total depth of the borehole. The logging analyst, EnergySolutions personnel, and the WRPS Closure and Corrective Measures Technical Lead will review the field log data. Based on the log data, up to two sampling intervals per site may be selected.

3.4 SAMPLING

After review of geophysical logging data and sampling zones have been selected, the push equipment will be relocated 2 to 3 ft away from the exploration borehole and sampling will be performed.

3.4.1 Sampling Process

The sampling process will entail a multiple sampling method as described in Section 2.3.

After retrieving the sampler to surface, the sampling system will be disassembled and the stainless steel liners will be removed for packaging and shipment to the designated laboratory. If opening of the retrieved sampler would result in more than the allowable dose rates per the Radiation Work Permit, the sampler will be placed in a transportation drum and opened under controlled conditions at the designated laboratory, or as directed by the Radiation Control organization.

3.4.2 Cleaning

Quality control requires that all materials (e.g., sample liners, material retaining baskets [finger baskets], sample caps) used for the performance of sampling activities be cleaned using U.S. Environmental Protection Agency guidelines/specifications as referenced in the RCRA. Cleaning of samplers, liners, etc., is the responsibility of the 222-S Laboratory personnel. WRPS Nuclear Chemical Operators will transport the clean sampling equipment to the job site. Equipment used for push advance purposes (e.g., push rods, tips) will be high-pressure washed using an approved non-phosphate cleaner. If it is not possible to remove the push equipment from the tank farm for cleaning, State of Washington, Department of Ecology has granted a variance to allow for hand cleaning and wiping of the rods to meet WAC cleaning requirements. The push equipment will be visibly free of dirt, grease, and other possible contamination which would potentially provide for cross-contamination of retrieved samples. After being cleaned, the equipment will be protected from contamination from surface chemicals and push operation-related chemicals. This protection will be accomplished by covering the materials with plastic or

RPP-RPT-56849, Rev. 0

GG-NW-DOW-001

Rev. 0

other acceptable materials, if necessary. The cleaned and protected equipment will be tracked by use of cleaning certification documentation.

3.4.3 Rinsate Samples

Field equipment rinsate blanks may be required for analysis purposes. This determination and collection of these rinsate samples is the responsibility of WRPS and their designated personnel.

3.5 FALLING HEAD TESTING AND BOREHOLE WALL MANIPULATION

There are up to six zones available for testing and up to four of these are currently planned for testing. All measurements, lengths of pipe placed, volumes of fluid added, and actions taken will be recorded on the daily Field Activity Report.

3.5.1 Falling Head Test

A desk instruction for the falling head activities shall be prepared to guide field actions. The falling head tests will be conducted by placement of an approximately 2 ft long screen section with a 6 in. to 1 ft long sump out through the end of the push tubing and will be centered within the zone of investigation. The screen and sump will be connected to surface by the PVC riser pipe. After placement of the screen and pipe, a piezometer will be positioned in the sump and connected to a computer at the surface. Up to 5 gallons of potable water will be introduced into the borehole and allowed to infiltrate into the borehole wall and formation while plotting the rate of decline of the height of water in the riser pipe (e.g., falling head). The onsite hydrologist will observe the data plots and provide direction regarding length of time for data collection, whether or not to repeat the test, and actions to be taken at the conclusion of the individual tests.

Graphs generated by plotting the head height vs. time will be utilized to calculate the borehole wall permeability. This data will be used to determine the net effect of the direct push methodology on formation permeability. Following the determination of effective permeability, (K), the borehole will be surged in an attempt to breakdown the compaction zone along the borehole wall.

3.5.2 Borehole Wall Manipulation (Surging)

When the onsite hydrogeologist has decided that the time vs. head height has reached "steady state" (i.e., the rate of change in the plotted curve is less than one), then the test will be terminated and the piezometer will be removed from the well. If necessary, additional water will be added to the well in order to assure that the zone of interest (screen interval) has a sufficient fluid height to cover the screen. The volume of water added to the well, will be recorded on the Field Activity Report. A slug rod will be inserted into the screen for surging the well. The screen zone will be surged by the up and down movement of the slug rod for up to 15 minutes and a measurement to determine the water level in the well will be performed. The onsite hydrogeologist will determine if additional water and surging is warranted, or if an additional falling head test should be conducted. These iterative steps of falling head testing and surging

RPP-RPT-56849, Rev. 0

GG-NW-DOW-001
Rev. 0

will be repeated until comparison of the generated test graphics indicate that the borehole wall permeability has been affected, or if no other additional actions are justified.

3.6 EXPLORATION AND SAMPLING BOREHOLE DECOMMISSIONING

Applicable requirements contained in WAC 173-160 will be used to control and guide actions for decommissioning the sampling and exploratory borehole. Each exploratory borehole and sampling hole will be filled with bentonite, a bentonite slurry, and/or grout (neat cement or cement-bentonite mixture) during the push rod extraction process. At the direction of the WRPS Closure and Corrective Measures Technical Lead, subsurface resistivity probes may be placed in the exploratory boreholes. Placement of the resistivity instrumentation and decommissioning materials used will be documented on the daily Field Activity Report and WAC Well Report.

4.0 ENVIRONMENTAL, SAFETY, AND HEALTH PROGRAM

The primary concern for EnergySolutions and the client (WRPS) is the safety of personnel assigned to perform activities related to the SX Pore Water Extraction Stage I work. These issues are addressed and all EnergySolutions, WRPS, and applicable *Occupational Safety and Health Act of 1970* safety and health requirements are applied and adhered to during the field operations. An activity-specific job hazard analysis outlines the specific activity hazards and the mitigation methodologies. The documentation governing the operation of the direct push rig, sampling, and decommissioning activities (JHA-GG-NWOP-RO-1858, Hanford SX Tank Farm Pore Water Extraction Stage I) is included as a portion of the WRPS tank farm work package.

Both EnergySolutions Safety personnel and WRPS Tank Farm Industrial Hygiene and Safety personnel will survey the job site for safety and health compliance. EnergySolutions personnel and safety representatives will provide onsite inspections and visits during drilling, sampling, and decommissioning/construction activities to ensure compliance with the Job Hazard Analysis. Routine inspection reports will be provided to the WRPS Closure and Corrective Measures Technical Lead.

EnergySolutions subscribes to the Integrated Safety Management System and has implemented an Integrated Safety Management System approach into all of its work tasks. These requirements flow down, not only internally to EnergySolutions employees but also to EnergySolutions subcontractors. All of the following requirements are in effect and will be observed, enforced and followed.

- Safety rules and procedures for safe job performance.
- Radiological Work Permit.
- WAC 173-160, as amended.
- *Occupational Safety and Health Act of 1970*.
- Client-identified standards.

RPP-RPT-56849, Rev. 0

GG-NW-DOW-001
Rev. 0

These requirements are communicated to everyone associated with the project (visitors included) using the WRPS Job Hazards Analysis checklist prepared by EnergySolutions Safety personnel. This Job Hazards Analysis checklist meets the EnergySolutions Environmental, Safety, and Health (ES&H) Program requirements. This program encompasses environment, safety, and health, including pollution prevention and waste minimization. All work for this project will be conducted in accordance with the five core functions of the EnergySolutions Integrated Safety Management System. These core functions are:

- Define the scope of work
- Identify the work hazards and ES&H requirements
- Analyze the work hazards and implement controls
- Perform the work activity within the developed controls
- Provide feedback on the adequacy of controls and safety management improvement.

The specific procedures used to accomplish these core functions are found in the EnergySolutions ES&H Program.

4.1 ENVIRONMENTAL, SAFETY, AND HEALTH PROGRAM KEY ELEMENTS

- Line management is responsible for the protection of employees, the public, and the environment.
- Clear and unambiguous lines of authority and responsibility for ensuring ES&H are established and maintained at all organizational levels.
- Personnel have "stop work" authority.
- Personnel possess the experience, knowledge, skills and abilities that are necessary to discharge their responsibilities.
- Resources are effectively allocated to address ES&H, programmatic, and operational considerations. Protecting employees, the public, and the environment is a priority whenever activities are planned and performed.
- Before work is performed, the associated hazards are evaluated and an agreed-upon set of ES&H standards and requirements is established which, if properly implemented, provides adequate assurance that employees, the public and the environment are protected from adverse consequences.
- Administrative and engineering controls to prevent and mitigate hazards are tailored to the work being performed and associated hazards. Emphasis should be on designing the work and/or controls to reduce or eliminate the hazards and to prevent accidents, unplanned releases, and exposures.

RPP-RPT-56849, Rev. 0

GG-NW-DOW-001
Rev. 0**4.2 WRPS-REQUIRED ENVIRONMENTAL, SAFETY, AND HEALTH ELEMENTS**

WRPS has provided a comprehensive list of WRPS, DOE, and Hanford Site-specific procedures and requirements for conducting work within the confines of the S-SX WMA. While executing the work scope detailed in this DOW, EnergySolutions will comply with all applicable directives and orders resulting from WRPS requirements.

5.0 QUALITY ASSURANCE

All work performed for the WRPS shall be based on the requirements of:

- Title 10 of the Code of Federal Regulations, Part 830, Subpart A (10 CFR 830, Subpart A), *Quality Assurance Requirements*.
- DOE Order 414.1C, *Quality Assurance*, for facilities and projects with the scope of work.
- NQA-1-2004, *Quality Requirements for Nuclear Facility Applications*.

EnergySolutions will conduct work in accordance with the EnergySolutions Quality Assurance Program, to specific work procedures and to this work plan.

**DESCRIPTION OF WORK: SX PORE WATER EXTRACTION
STAGE III****1.0 INTRODUCTION AND BACKGROUND****1.1 GENERAL DESCRIPTION**

There are 177 large, underground tanks located at the Hanford Site, 149 of them are single-shelled. These tanks and their associated facilities are grouped into 12 “tank farms.” The tanks were used for storage of some of the most dangerous and hazardous waste produced during the processing of irradiated fuel to obtain plutonium. Tank farms were located downhill from chemical separations plants so that the wastes would gravity-flow to the tanks. Six single-shell tank (SST) farms (241-S, 241-SX, 241-T, 241-TX, 241-TY, and 241-U) are located in the 200 West Area of the Hanford Site. This Description of Work (DOW) focuses on the SX tank farm and an investigation related to extraction of potentially contaminated pore-water from under and adjacent to the SX tank farm. This DOW provides the work instructions for conducting characterization, logging, oversight, and documentation efforts for continuing activities related to SX Pore Water Extraction as listed in RPP-PLAN-53808, *200 West Area Tank Farms Interim Measures Preliminary Investigation Work Plan*, Rev. 1 or latest revision. The scope of work includes: providing equipment and personnel to conduct direct push activities; providing safety oversight; providing geophysical logging services; procuring and installing packer and screen assemblies; performing falling head tests and borehole wall manipulation activities in screened areas of the boreholes; attending meetings and planning sessions; and providing a written report documenting field activities and data collection at the conclusion of the scope of work. This work is being conducted at the direction of Washington River Protection Solutions (WRPS) Closure and Corrective Measures group.

1.2 BACKGROUND

The U.S. Department of Energy (DOE) assigned the River Protection Project (RPP) Single-Shell Tank Program the tasks of transferring waste from the SST to double-shell tanks, and developing and implementing a strategy to retrieve SST waste and miscellaneous underground storage tank waste. The WRPS Closure and Corrective Measures group was given responsibility for collecting and providing subsurface data from the SST farm facilities. This contributes to preparation for the eventual retrieval of the tank waste. The intent of the SST Waste Management Area (WMA) characterization program is to collect and analyze samples to provide an understanding of the distribution and movement of contaminants in the vadose zone under and adjacent to the tank farms. These SST farms are designated as Radiological Buffer Areas or Contamination Areas.

The SX tank farm is believed to have been associated with tank waste losses to the soil column as a result of overfilling, leaks from ancillary equipment, and/or leaks from the tanks themselves.

RPP-RPT-56849, Rev. 0

PL-36472-OP-0002

Rev. 0

Detailed estimates of soil waste inventories have been prepared for this tank farm and are documented in various reports identified in RPP-PLAN-53808.

The purpose of the Pore Water Extraction testing is to determine if the technology has potential to remediate identified contamination. Stage I initial actions characterized the study area, provided for selection of a test site, and gathered location-specific technical information of the lithology for performing a proof-of-principle extraction test.

Results of previous soil investigations at SX tank farm have documented the presence of nitrate and technetium-99 contamination within the vadose zone. The most effective way to mitigate risk associated with this contamination is through restriction of groundwater recharge using interim surface barriers or removing contaminants in the vadose. RPP-7884, *Field Investigation Report for Waste Management Area S-SX*, indicates future risk is best mitigated by reducing both the subsurface moisture content and the soil contaminant inventory. Previous work completed at T and TY tank farms resulted in the installation of interim surface barriers to reduce soil moisture. The work planned in this document evaluates the potential to reduce the subsurface soil moisture and contaminant inventory through pore water and vapor extraction.

Recent logging and sampling performed under GG-NW-DOW-001, *Description of Work: SX Pore Water Extraction - Stage I* (also includes Stage II), determined that sampled zones in the Cold Creek had sediment types that met Pacific Northwest National Laboratory modeling criteria for suitability for pore water extraction, the targeted sediments were of sufficient thickness to be viable candidates for extraction, and sampling results contained detectable levels of nitrates that would prove/demonstrate the viability/success of the technology at this location.

1.3 TANK FARM BACKGROUND

The SX tank farm was constructed between 1953 and 1954 and consists of 15 SSTs. The 241-SX tanks are arranged in rows of three tanks each, downhill from the chemical separations plants, each tank at a slightly lower elevation than its neighbor so that the wastes gravity-flow into the tanks. Each of the 241-SX tanks has a nominal one million gallon storage capacity, and consists of a carbon steel liner inside a reinforced concrete shell. The steel tank liner covers the 75-ft inner diameter tank bottom and sidewalls to a height of approximately 32 ft as measured from the tank center. The tank bottom is dish-shaped and slopes approximately 3.3% from the sidewall to the tank center (i.e., 14.875-in. elevation drop over 37.5-ft radius).

Ten of the tanks in the SX tank farm have laterals (cased borings) installed below the tank bottoms as part of the leak detection system. In addition to laterals, vadose zone monitoring wells (drywells) are installed throughout the tank farm for leak detection.

RPP-RPT-56849, Rev. 0

PL-36472-OP-0002
Rev. 0

1.4 PHYSICAL SETTING

The SST tank farms were constructed in excavations into the near-surface sediments that overlie the Columbia River Basalt Group. The Columbia River Basalt forms the basement bedrock. There are approximately 169 to 179 m (555 to 590 ft) of continental sediments that overlie the basalt in WMA S-SX. From oldest to youngest, these deposits include the following.

- Columbia River Basalt Group
- Ringold Formation
- Cold Creek unit – lower carbonate rich sequence (CCU_l)
- Cold Creek unit – upper silt and sand sequence (CCU_u)
- Hanford Formation – lower fine sand and silt sequence (H2 subunit)
- Hanford Formation – middle coarse sand and gravel sequence, upper fine sand, and top gravelly sand sequence (H1 subunit)
- Backfill

The general characteristics of these units are described in more detail in RPP-23748, *Geology, Hydrogeology, Geochemistry, and Mineralogy Data Package for the Single-Shell Tank Waste Management Areas at the Hanford Site*. All of the formations, except for the surface of the Hanford formation, have a general tendency to dip west to southwest toward the axis of the Cold Creek unit. The SSTs at WMA S-SX were placed within the Hanford formation sediments of an upper sand-dominated (H1) subunit, and may locally intercept the upper portions of a middle gravel-dominated Hanford (H1) unit. The vadose zone beneath WMA S-SX is as much as 65 m thick (213 ft) and consists of the Hanford formation, the Cold Creek unit, and the upper part of the Ringold Formation. Both the water table and the unconfined aquifer reside entirely within the Ringold Formation.

Sediments in the vadose zone vary from open-framework gravels of the gravel-dominated facies and interbedded sand and silt of the silt-dominated facies of the Hanford formation to calcium carbonate-rich deposits of the Cold Creek unit and cemented gravels of the Ringold Formation. These sediments are characterized by numerous lateral discontinuities, such as pinch outs, erosional truncations, and irregular flow patterns. If clastic dikes are present, they may enhance vertical flow patterns. Therefore, there are numerous possible avenues for contamination to migrate through the vadose zone (HNF-4936, *Subsurface Physical Conditions Description of the S-SX Waste Management Area*).

2.0 WORK SCOPE

EnergySolutions Government Group, Northwest Operations (EnergySolutions) will utilize a direct push technology to place testing pushes at four sites south of the 241-SX tank farm. At these sites, the testing boreholes will be driven to approximately 150 ft below ground surface (bgs). Volume reduction will be performed in three back to back actions in each of the four boreholes through the anticipated zone of interest. The boreholes will be utilized for collection of remote sensing geophysical log data. Gamma information and volumetric water

RPP-RPT-56849, Rev. 0

PL-36472-OP-0002

Rev. 0

content will be collected with standard logging suites. These logging suites consist of a combination tool of lanthanum bromide and bismuth germinate oxide (LaBr/BGO) for gross gamma and spectral gamma analysis, and a neutron-neutron detector.

After log data collection and processing, the data will be reviewed to:

- Determine if the sediment type and bedding thickness are sufficient to meet extraction goals
- Identify the borehole to be used for extraction and the three boreholes to be used for monitoring boreholes
- Identify the precise depth for placement of the screen and packer assemblies.

WRPS Project Management and technical representatives and various subcontractors supporting the project will participate in performance of the above determinations.

After logging is complete, a well screen and packer assembly will be placed in the zone of interest in each well. Testing and well development will be performed. Section 3.5 contains a detailed description of the planned actions.

After the testing and well development activities have been completed, surface seals and connections to the surface extraction system will be installed. Section 3.0 provides more details on the screen and packer assemblies and information on the falling head tests, and borehole wall/formation development.

2.1 METHOD FOR BOREHOLE PLACEMENT

The method selected for borehole placement is a hydraulic hammer-driven push system on a tractor or track mounted-type carrier. The locations for investigation have been selected based on their relationship/proximity to C8761. The arrangement of the four boreholes in a 4 x 8 ft "box" is based on a multi-use intention that will allow any of the four locations to be utilized as an extraction well or monitoring well. Geophysical logging information will be used to determine which location will be used for monitoring or extraction.

The boreholes will be pushed using outer push tubing that is 6.67 cm (2.625-in.) OD x 4.76 cm (1.875-in.) ID and inner tubing that is 3.81 cm (1.5-in.) OD x 2.54 cm (1.0-in.) ID. This push method was chosen to reduce the compaction of the borehole wall during the driving process. Additional efforts to reduce the volume of materials compacted into the borehole wall, as the tip advances, will be accomplished by use of the dual wall sampling system to remove soil volume from the center of the borehole as the tubing is advanced through the area of interest. Three volume reduction runs (each of about 24 in. in length) will be conducted (back to back) from 124 to 130 ft bgs, using the standard device for sampling. The recovered material will not be analyzed and will be disposed of in an onsite waste barrel.

The dual wall sampling system holds three stainless steel liners that are 3.17 cm (1.25-in.) OD x 2.7 cm (1.08-in.) ID. After the sampling system is advanced approximately 0.6 m (2 ft), the inner

RPP-RPT-56849, Rev. 0

PL-36472-OP-0002

Rev. 0

string is released and retrieved to surface. The liners will be removed from the sampling system, surveyed, and placed into a disposal container.

After the volume reduction runs, the dummy tip will be re-inserted and the tubing will be driven to a total depth of approximately 150 ft bgs or refusal (whichever occurs first). Geophysical logging with LaBr/BGO gamma and neutron-neutron moisture instrumentation will be conducted. Data from the moisture and gamma logs collected from the borehole will be used by the WRPS Closure and Corrective Measures and EnergySolutions technical personnel to determine the precise location for the placement of the extraction assemblies.

2.2 PLACEMENT OF BOREHOLES

The general location for the four prospective test locations, in relation to 200 West Area and the Hanford Site, is shown in Figure 2-1. Ground penetrating radar (GPR) and electrical ground scans will be performed before boreholes are pushed to identify subsurface infrastructure and support citing of the test boreholes. The combination of subsurface infrastructure and surface accessibility will be used to determine the exact location of each borehole. The push location will be staked by use of Global Positioning Satellite equipment and verified by a licensed land surveyor.

Table 2-1 contains the proposed coordinates and borehole numbers associated with each borehole location. Figure 2-2 shows a close-up location of the boreholes showing the southern fence line of SX tank farm.

Table 2-1. Coordinates of Boreholes for Stage III.

Site #	Borehole #	Northing	Easting
1	C8823	134133.3	566824.1
2	C8824	134133.2	566825.3
3	C8825	134130.8	566825.1
4	C8826	134130.8	566823.9

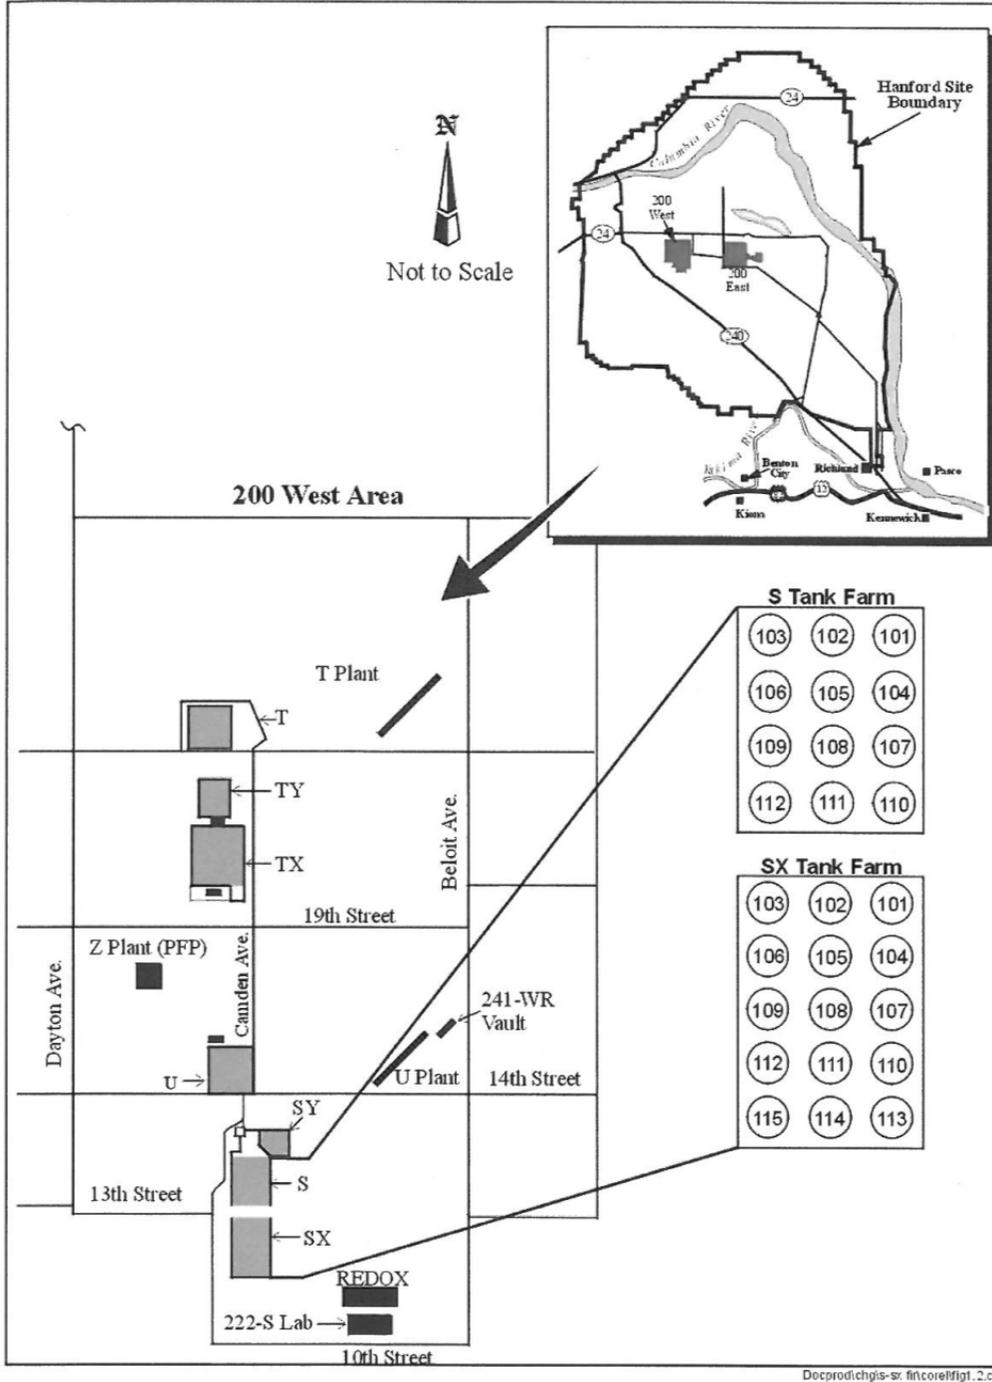

2.2.1 Push Location Documentation

These locations were selected through an iterative process using GPR data and review of as-built infrastructure drawings. The infrastructure interferences were reviewed from available drawings and site walk downs and this data was utilized for review of the GPR data. Based on this iterative process, four proposed push site locations were identified.

RPP-RPT-56849, Rev. 0

Rev. 0

Figure 2-2. Site Map.

RPP-RPT-56849, Rev. 0PL-36472-OP-0002
Rev. 0

The final coordinates of the selected sites were then plotted with computer-aided drafting. The push locations are documented above (see Table 2-1). In addition to the coordinate position of each push location, the push depth, geophysical log data, and other pertinent information derived during the activity (e.g., depth of contamination as identified from geophysical log interpretation and degree of contamination observed on push rods during extraction) is included in the Field Activity Reports and State of Washington, Department of Ecology-required documentation.

2.2.2 Push Location Tables And Numbering

All push location activities are tracked and documented on Field Activity Reports by referencing the Well identification (Well ID) number as provided in Table 2-1 or assigned during progress of the work. The unique Well ID numbers for push locations have been assigned and listed for use during the Stage III SX Pore Water Extraction Test by the Hanford Site Well Coordinator.

3.0 WORK TASKS**3.1 SITE SETUP**

The push equipment will be mobilized and a controlled work area set up surrounding the preselected and marked location. A radiological pre-survey of the tractor and equipment will be conducted (per WRPS procedure) prior to moving the equipment into the work zone. As noted above, GPR scans and as-built drawing reviews and comparisons have been completed to properly select the push location. The push equipment consists of a tractor-mounted mobile unit with a hydraulically-powered hammer and mast system. Support equipment to be used during field activities will be mobilized into the work area as needed. A forklift will transport needed support equipment to and from the push locations. Tank farm personnel will provide support, as necessary, for guiding the equipment onto location and for subsequent movement of the equipment to other locations.

WRPS Radiological Control Technicians and Nuclear Chemical Operators will be onsite to support work during activities that create potential personnel exposure. Contamination control measures will consist of laying spill protection material beneath the equipment (when required). Spill protection consists of felt and plastic sheeting placed on and around the direct push unit when necessary and prudent. Control of the work area and control of potential contamination are aided by restricting site entries by unnecessary personnel. WRPS Health Physics personnel will provide direction and support to ensure radiological protection is maintained for all personnel associated with the work.

3.2 PRECAUTIONARY MEASURES

During advancement of the boreholes, casing (push rods) will be driven into the subsurface by use of the hydraulic hammer impact system. The push locations have been positioned to avoid impacting known/mapped structures. Careful observation of the push advance rates and

RPP-RPT-56849, Rev. 0

PL-36472-OP-0002
Rev. 0

resistance will be observed to preclude damage to any tank farm infrastructures should the as-built drawings be erroneous. If rod advance indicates that obstructions are present, push advance will stop, the direct push equipment and work area will be placed in a safe condition and the Closure and Corrective Measures Technical Lead or his designee, and the WRPS field work supervisor will be notified. If during push operations, a borehole is deemed to be “at refusal” as defined by trained operators of the direct push equipment (refusal is defined as a minimum of one inch of advance per minute of impact operations), the length of tubing driven will be noted in the Field Activity Report and a decision made by the Closure and Corrective Measures Technical Lead, or his designee, as to whether the borehole is deep enough for falling head testing or if it must be decommissioned.

All activities using the hammer unit will conform to the manufacturer’s operating manual and applicable procedures and work package instructions that relate to the specific phase of work. As the push rods are extracted from the boreholes, the onsite Health Physics Technician will monitor for radiological contamination. WRPS tank farm-qualified Nuclear Chemical Operators will perform any decontamination required. The sealing requirements for decommissioning of the boreholes are defined in the appropriate sections of the Washington Administrative Code (WAC) 173-160.

3.3 GEOPHYSICAL LOGGING

EnergySolutions will conduct logging operations to gather geophysical information. These geophysical investigations will be conducted in conformance with EnergySolutions procedure GG-NW-FA-PR-001, *Geophysical Logging* and the EnergySolutions document ESTP-QA-PN-001, *Engineered Systems and Technology Projects – Quality Assurance Program Plan*. Logging parameters may be changed and/or log suites may be added or deleted based on the technical needs of the project, as determined by the WRPS Closure and Corrective Measures Technical Lead. The following logging suites are planned:

1. Lanthanum Bromide/Bismuth germinate oxide (LaBr/BGO) @ 100 seconds/0.5 ft
2. Additional logging with the “Red” and/or “Green” Geiger/Muller equipment, if necessary, based on observed results
3. Neutron-Neutron detector with a client (WRPS)-provided Americium Beryllium source for moisture logging @ 15 seconds/0.25 ft

Logging data will be collected from 150 ft to 90 ft bgs in each borehole. The logging analyst, EnergySolutions personnel, and the WRPS Closure and Corrective Measures Technical Lead will review the log data and select the locations for the falling head tests.

3.4 MONITORING AND EXTRACTION WELL PLACEMENT

These extraction wells will be initially driven utilizing the 2 5/8 in. OD dual wall tubing system. When the boring is advanced through the zone of interest, actions to reduce the amount of soil displaced into the side wall of the hole will be conducted. This will be accomplished by

RPP-RPT-56849, Rev. 0

PL-36472-OP-0002
Rev. 0

advancing the soil sampling system through the interval. This material will not be analyzed and will be discarded into a waste barrel. This soil removal activity is intended to decrease the volume of material displaced into the borehole wall and increase the potential improvement in borehole wall permeability gained by the well development actions. After the well has advanced to the planned total depth of approximately 150 ft bgs, or met refusal, the entire casing/tubing string will be removed and replaced with a single use design with an expanded 2 5/8 in. open throat point holder with a disposable tip. This system will then be re-driven to refusal or the original total depth. This set of actions will be conducted in each of the four borings.

Each of the four borings will have a sump, and a well screen and packer assembly placed in the zone of interest, as determined from review of geophysical log data and correlation to the nearby characterization borehole (C8761). Figure 3-1 shows a depiction of a successful as-built condition for placing and cementing a packer and well screen assembly.

3.5 FALLING HEAD TESTING AND BOREHOLE WALL MANIPULATION

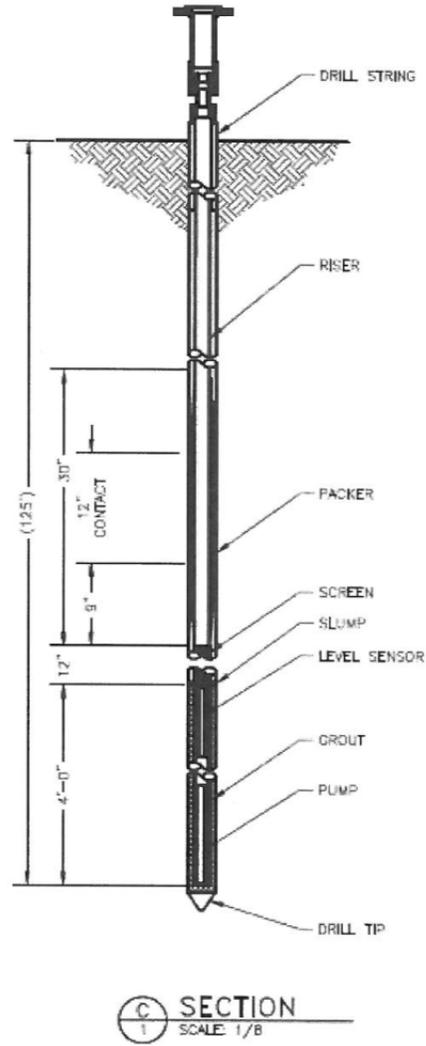

Four zones of interest (one in each borehole) will be developed after the screen and packer assemblies have been placed, cemented, and have undergone sufficient curing time to have reached a non-deformable state. The development is designed to breakdown the compaction zone created along the borehole wall by displacement of soil materials as the direct push probe is advanced. A desk instruction for falling head testing and borehole wall manipulation will direct the field activities. All measurements, lengths of pipe placed, volumes of fluid added, and actions taken will be recorded on the daily Field Activity Report.

The screen and packer assembly will be placed, cemented, and allowed to cure before additional activities are undertaken. The cure time for the cement will be determined by placing a sample of the cement mix in a container at surface. When the sample cement is observed to be non-deformable, a pressure transducer will be placed near the top of the well sump, and an initial falling head test will be conducted prior to attempting any borehole wall compaction zone modification. Up to two gallons of potable water will be introduced into the borehole and allowed to infiltrate into the borehole wall and formation while the rate of decline of the height of water in the riser pipe (e.g., falling head) is recorded on a surface computer. The field hydrologist will observe the data plots and direct the length of time for data collection. It is currently estimated that this test will require between four and eight hours to complete. Graphs generated by plotting the head height vs. time will be utilized to calculate the borehole wall permeability. This data will be used to determine the net effect of the direct push methodology on formation permeability.

RPP-RPT-56849, Rev. 0

PL-36472-OP-0002
Rev. 0

Figure 3-1. Packer and Screen Assembly.

RPP-RPT-56849, Rev. 0PL-36472-OP-0002
Rev. 0

Following the determination of effective permeability (K), the transducer will be removed, additional water will be added, and the borehole will be surged for a prescribed period of time. Debris produced during this surging will be removed, and additional water will be added as necessary to facilitate pumping and removal of the debris produced through the well screen in an attempt to breakdown the compaction zone along the borehole wall. After a number of repetitions (adding water, surging, and water and debris removal), the pressure transducer will be repositioned in the well and a second falling head test will be conducted. The estimate for this test is one hour in duration. The initial shape of the draw-down (head decline) curve will be sufficient to determine if the surging has created the desired effect and has sufficiently enhanced the borehole wall permeability to provide sufficient connection to the undisturbed formation for conducting extraction activities. The hydrology consultant will prepare comparative graphs for use in determining the relative success of the borehole wall development actions.

3.6 EXPLORATION AND SAMPLING BOREHOLE DECOMMISSIONING

At the conclusion of surging and testing activities, the surface treatment specified by the vacuum extraction equipment design contractor will be added to the riser and the well will be secured. The wells will be held in this condition for further testing and will not be decommissioned until directed by WRPS Project Management.

Applicable requirements contained in WAC 173-160 will be used to control and guide actions for drilling, construction, and subsequent decommissioning actions at the conclusion of water extraction testing. Given that these are not normal well placements, a variance to WAC 173-160 rules will be requested prior to the initiation of drilling. When directed by WRPS, each borehole will be filled with bentonite, a bentonite slurry, and/or grout (neat cement or cement-bentonite mixture) during the outer casing extraction process after filling the sump, screen, and inner riser pipe with bentonite. All decommissioning materials used, depth of placement, and other actions will be documented on the daily Field Activity Report and WAC Well Report.

4.0 ENVIRONMENTAL, SAFETY, AND HEALTH PROGRAM

The primary concern for *EnergySolutions* and the client (WRPS) is the safety of personnel assigned to perform activities related to the SX tank farm work. WRPS has provided a comprehensive list of WRPS, DOE, and Hanford Site-specific procedures and requirements for conducting work within the confines of the SX tank farm. While executing the work scope detailed in this DOW, *EnergySolutions* will comply with all applicable directives and orders resulting from WRPS requirements, DOE, and Hanford Site procedures.

RPP-RPT-56849, Rev. 0

PL-36472-OP-0002
Rev. 0**4.1 ENERGYSOLUTIONS INTEGRATED SAFETY MANAGEMENT SYSTEM KEY ELEMENTS**

EnergySolutions subscribes to the Integrated Safety Management System (ISMS) and has implemented an ISMS approach into all of its work tasks. These requirements flow down, not only internally to EnergySolutions employees but also to EnergySolutions subcontractors. All of the following are in effect and will be observed, enforced and followed.

- WRPS safety and health standards, procedures, and permits.
- 10 CFR 851
- WAC 173-160, as amended.
- *Occupational Safety and Health Act of 1970.*
- EnergySolutions safety and health standards, procedures, and permits.

4.1.1 Integrated Safety Management System Core Functions

This ISMS program encompasses environment, safety, and health, including pollution prevention and waste minimization. All work for this project will be analyzed in accordance with the five core functions of the EnergySolutions ISMS:

- Define the scope of work.
- Identify the work hazards and Environmental, Safety, and Health (ES&H) requirements.
- Analyze the work hazards and implement controls.
- Perform the work activity within the developed controls.
- Provide feedback on the adequacy of controls and safety management improvement.

4.1.2 Integrated Safety Management System Key Elements

The ISMS guiding principles describe the environment or context for work activities in that most principles apply to each and every ISMS core function. The guiding principles are:

- Line management is responsible for the protection of employees, the public, and the environment.
- Clear and unambiguous lines of authority and responsibility for ensuring ES&H are established and maintained at all organizational levels.
- Personnel have “stop work” authority.
- Personnel possess the experience, knowledge, skills, and abilities that are necessary to discharge their responsibilities.
- Resources are effectively allocated to address ES&H, programmatic, and operational considerations. Protecting employees, the public, and the environment is a priority whenever activities are planned and performed.
- Before work is performed, the associated hazards are evaluated and an agreed-upon set of ES&H standards and requirements is established which, if properly implemented, provides

RPP-RPT-56849, Rev. 0

PL-36472-OP-0002
Rev. 0

adequate assurance that employees, the public, and the environment are protected from adverse consequences.

- Administrative and engineering controls to prevent and mitigate hazards are tailored to the work being performed and associated hazards. Emphasis should be on designing the work and/or controls to reduce or eliminate the hazards and to prevent accidents, unplanned releases, and exposures.

4.2 JOB HAZARD ANALYSIS

WRPS has prepared a general hazard analysis (GHA) that applies to all personnel employed by WRPS or subcontracted to WRPS on the Hanford site. This hazard analysis identifies routine industrial safety hazards where employee training and knowledge are considered sufficient to implement skill-based controls.

In addition to the GHA, *EnergySolutions* has coordinated with WRPS Industrial Hygiene and Safety oversight to prepare a standing job hazard analysis (SJHA-0080) for Vadose Direct Push activities located inside/around WRPS tank farms; encompassing the hydraulic hammer unit direct push activities to be conducted during this scope of work. *EnergySolutions* personnel performing these activities have been provided the appropriate training and instruction to mitigate these hazards. The requirements of the WRPS GHA and SJHA are communicated to everyone associated with the project, including visitors.

4.3 SAFETY AND HEALTH COMPLIANCE OVERSIGHT

Both *EnergySolutions* Safety personnel and WRPS Tank Farm Industrial Hygiene and Safety personnel may survey the job site for safety and health compliance. *EnergySolutions* safety representatives, in coordination with WRPS Tank Farm Industrial Hygiene and Safety personnel, will provide onsite inspections and visits during the drilling, sampling, and decommissioning/construction activities to ensure compliance with health and safety regulations and WRPS health and safety procedures. Routine inspection reports will be provided to the WRPS Closure and Corrective Measures Technical Lead.

5.0 QUALITY ASSURANCE

All work performed for the WRPS shall be based on the requirements of:

- Title 10 of the Code of Federal Regulations, Part 830, Subpart A (10 CFR 830, Subpart A), *Quality Assurance Requirements*.
- DOE Order 414.1C, *Quality Assurance*, for facilities and projects with the scope of work.
- NQA-1-2004, *Quality Requirements for Nuclear Facility Applications*.

RPP-RPT-56849, Rev. 0

PL-36472-OP-0002
Rev. 0

EnergySolutions will conduct work in accordance with the *Engineered Systems and Technology Projects – Quality Assurance Program Plan*, to specific work procedures, and to this work plan.

TIME	WORK SUMMARY			
0600	Safety meeting at office. Topic: Nitrogen Safety.			
0717	Travel to SMURF for P.O.D.			
0753	Onsite at SMURF. P.O.D. at SMURF by R. Franzen FWS WRPS. NOTE: No 8-Point Criteria Checklist is in the work package yet.			
0815	"ACE" under RWP CO-762 at SMURF and travel to "SX" Tank Farm.			
0830	Onsite at "SX" Tank Farm. Standby for NCO's and HPT's. Inspect and warm equipment. No problems noted.			
0845	NCO's onsite. Set-up boundary around work site.			
0905	Pushed boring #C8757 from GS to refusal at 11.5' BGS. Notified R. Franzen WRPS FWS.			
0930	Standby for direction from WRPS.			
1000	Directed by WRPS to decommission #C8757 and rename it #C8757A. HPT's and NCO's set-up RBA and RCA around tubing.			
----	Back-pulled 2-4' joints of 2.5" tubing. Unable to back-pull remaining tubing. Needed to change from 2.5" drive head to 2.5" back-pulling head. There is no 8-Point Criteria Checklist in the work package to allow us to make the change. RCA was left around the tubing and the site was secured.			
1045	Standby for 8-Point Criteria Checklist to be added to the work package.			
1115	Lunch.			
1145	Standby for 8-Point Criteria Checklist to be added to the work package. NOTE: 8-Point Criteria Checklist was received at 1400 Hrs.			
1415	No HPT's returned to "SX" Tank Farm and we are unable to complete decommissioning #C8757A. Traveled to office. Completed paperwork and timecard.			
1530	End of shift.

TIME	WORK SUMMARY			
0600	Safety meeting at office. Topic: Driver Conduct at Accident Scene.			
0715	Travel to MO563 in 200W for P.O.D.			
0745	On site waiting for POD			
0800	POD: Franzen, FWS, WRPS, 8-point criteria, hole location, Forklift availability, Hoist keeping. Decision was made to calibrate logging equipment due to no forklift available to move pipe out of the way so the rig can be moved. The hole will be moved 3 feet south of the original hole per Mike Walkups direction.			
0830	need to get rods to insert Russ and try to calibrate tooling			
0845	waiting on Support at cal rods.			
1035	Decision was made to go back to SX and pull pipe. Can't get sensor to calibrating. Head to SX			
1100	waiting on RCT's			
1130	RCT's on site, take lunch			
12:00	waiting for RCT's			
1240	RCT's on site, go to rig, was on up, and pull rods. MGW was 97 then 100 feet, and try again.			
1250	Enter site and pull rods out of C8757B			
1315	Moved rig, begin pushing on C8757			
1325	Hit refusal at 11.5 feet, waiting on call to move.			
1415	Rick Franzen called Harold, still no answer called the day.			
1430	Head to office decommission.

TIME	WORK SUMMARY		
0600	Safety meeting at office. Topic: Smoke Detectors-A Life Saving Warning.		
0645	Travel to "SX" Tank Farm.		
0715	Onsite at "SX" Tank Farm. Standby for P.O.D.		
0745	No P.O.D. was given by R. Franzen FWS for WRPS. IH technicians were questioning their qualifications for doing the required		
-----	sampling activities. Also in question was the length of tubing required and their instruments capability of handling it. ESGG crew		
-----	placed on standby.		
1100	Lunch		
1130	ESGG crew on standby waiting for determination from IH technicians.		
1230	Travel to office. Complete paperwork and timecard. ESGG crew still on standby.		
1530	End of shift.

TIME	WORK SUMMARY			
0600	Safety meeting at office. Topic: Machine Safety-Requirements For Safeguards			
0700	Head to site AT SX			
0730	On site, waiting on POD			
0800	Rick Franzen on site, bought a letter in from Jenni for Dobb saying we should have a decision by 9:00. (Standby)			
0915	Green light from Jennife Dobb to go ahead and sample the hole by IH Tech. Standby waiting for POD and IH			
1008	IH on site, Annette (ESCC safety) on site, Rick will now hold POD. N			
1015	No POD yet, IH had to go get his instrument and ACE in (STANDBY)			
1030	POD - Sampling hole by IH (Air Sample and background Air samples were the topics.			
1040	AT Rig, IH pulling air samples.			
1105	Back ground samples complete, run sampling tube in hole. N			
1130	No hits at 10 feet lowered tubing to 120 feet. Meter checked out at 99.73 PPM. (don't know what it is)			
1145	SHut down site, cap hole until they figure out what to do next. Leave site and head to yard to round up material			
1430	Head to office			
1500	Paper work			
1530	End shift

TIME	WORK SUMMARY			
0600	Safety meeting at office. Topic: Preventing Strains & Sprains.			
0645	Travel to MO 563 for P.O.D.			
0715	Onsite at MO 563. Standby for P.O.D.			
0815	P.O.D. was held by R. Franzen FWS WRPS. A safety concern was raised about the previous air sample reading at ~120.0' BGS in boring #C8760. The previous air sample obtained showed a reading of ~100 PPM of an unknown origin. The decision was made by R. Franzen FWS for WRPS to have the IH Technicians to obtain another air sample and take it to the SMURF building for analysis. The air sample and an exhaust of the HHU XL after initial startup was taken at ~1000 Hrs. The air sample in boring #C8760 at ~120.0' BGS was collected and taken for analysis.			
1000	ESGG crew on standby awaiting the air sample analysis results.			
1100	Lunch.			
1130	ESGG crew on standby awaiting the air sample analysis results. Traveled to office. Completed paperwork and timecard.			
1530	End of shift.

TIME	WORK SUMMARY	
0600	Safety meeting at office. Topic: This'll Kill You.	
0630	Travel to MO 563 for P.O.D.	
0715	Onsite at MO 563. Standby for P.O.D.	
0800	P.O.D. was held by R. Franzen FWS WRPS.	
0815	"ACE" under RWP CO-762 Rev. 3 at MO 563.	
0845	Fuel, inspect and warm HHU XL. No problems noted.	
0900	Ran inner string and dummy tip back in sample boring #C8760 and drove to original TD at 127.0' BGS. Inner string and dummy tip	
-----	were left in the boring and the boring was capped.	
0925	Moved HHU XL and support equipment to sample boring #C8762 and set-up.	
0955	Drove dual wall with dummy tip from GS to 18.0' BGS.	
1100	Lunch.	
1130	Drove dual wall with dummy tip from 18.0' BGS to 29.0' BGS.	
1200	Stopped and let crossover sub. and drive head cool.	
1230	Drove dual wall with dummy tip from 29.0' BGS to 49.0' BGS.	
1300	Stopped and let crossover sub. and drive head cool.	
1320	Drove dual wall with dummy tip from 49.0' BGS to 57.0' BGS.	
1340	Stopped and let crossover sub. and drive head cool.	
1405	Drove dual wall with dummy tip from 57.0' BGS to 69.0' BGS.	
1445	Stopped and let crossover sub. and drive head cool. Traveled to office. Completed paperwork and timecard.	
1530	End of shift.

TIME	WORK SUMMARY	
0600	Safety meeting at office. Topic: Emergency Warning Devices.	
0645	Travel to MO 563 for P.O.D.	
0715	Onsite at MO 563. Standby for P.O.D.	
0800	P.O.D. was held by R. Franzen FWS WRPS and "ACE" under RWP CO-762 Rev. 3	
0815	Inspect and warm HHU XL. No problems noted.	
0820	Move HHU XL and support equipment to boring #C8761 and set-up.	
0835	Back-pulled 2.5" casing from 152.0' BGS to 129.7' BGS. expendable tip was knocked out. Granular bentonite was added as casing was back-pulled.	
0855	Ran inner string and dummy tip in boring and reamed open the knock-out tip holder. Inner string and dummy tip were pulled.	
0950	10-20 mesh sand was added from 129.7' BGS to 129.2' BGS. 1 1/4" O.D. PVC well with sump and screen was installed in preparation for falling head testing. 2.5" casing was back-pulled from 129.2' BGS to 127.1' BGS to expose PVC well screen.	
-----	NOTE: See attached asbuilt for depth installation of materials.	
1100	Lunch.	
1130	R. Simpson onsite to begin falling head testing. Installed transducer in borehole. Falling head testing was initiated. 3 gallons of water was used for two tests. Transducer was left in borehole and testing ran overnight.	
1421	Secured site and travelled to office. Completed paperwork and timecard.	
1530	End of shift.

TIME	WORK SUMMARY			
0600	Safety meeting at office. Topic: The Intersection Problem			
0625	Travel to MO 563 for P.O.D.			
0705	Onsite at MO 563. Standby for P.O.D.			
0800	P.O.D. was held by R. Franzen FWS WRPS and "ACE" under RWP CO-762 Rev. 3			
0825	R. Simpson and ESGG crew continuing falling head testing in borehole. 1 1/4" PVC well screen was surged and bailed.			
-----	Tagged bottom of well at 129.2' before surging. Surged for 15 minutes. Retagged bottom of well at 129.3' BGS after surging.			
-----	Began bailing well to remove the remaining water and sediment from the previous test.			
1105	Lunch.			
1135	Continued bailing of well. Unable to remove the last 5.75' of water due to the sediment lodging in the bottom of the bailer.			
-----	Decision was made at the ESGG office to add 1/2 gallon of water to try and dilute the sediment. Well was then bailed down to a			
-----	depth of 0.174' of water remaining in the well sump.			
1400	Falling head activities were continued with the addition of 2 gallons of water. Transducer was placed in well and testing will			
-----	continue overnight.			
1415	Secured site and travelled to office. Completed paperwork and timecard.			
1530	End of shift.

Geophysical Logging in the 241-SX Tank Farm

1 Introduction

EnergySolutions (ES) and Three Rivers Scientific provided small diameter (slim hole) logging in support of field activities at the 241-SX Tank Farm. Logging surveys were conducted with three detectors: BGO, LaBr (both scintillation) and a neutron-neutron moisture tool. The surveys assisted in the identification of zones for sample collection and laboratory analysis, and vapor extraction tests. This report includes the results of these surveys for the two probeholes installed at the investigation site (see Appendix A).

The BGO and LaBr instruments were run in combination during the logging run, and spectral data were recorded for both. The energy resolution of the LaBr is superior to the BGO, but the BGO efficiency for KUT naturals is superior to the LaBr. Thus, the data from the BGO were used to measure gross gamma and concentrations of KUT, and the LaBr data was used to identify and measure the concentrations of selected radionuclides. The targeted radionuclide for this project was ^{137}Cs .

Both of the gamma tools were calibrated for the probehole conditions present at the investigation site. The moisture tool was calibrated to both 6 and 8 inch-cased calibration standards. A casing thickness correction was applied to the extrapolated casing diameter calibrations for the moisture response.

2 Survey Results

Log surveys were recorded from the bottom of the probehole (maximum survey depth) to the ground surface. Zero depth reference is at ground surface. A daily repeat measurement was acquired to verify instrument repeatability. The main log and repeat intervals are presented on the same plot. The computed results of the main and repeat intervals were reviewed and the results agree within the uncertainty of the measurement counting statistics.

The survey results for each probehole are presented as a depth versus concentration plot in Appendix A.

3 Geophysical Logging System

The logging system is a portable unit powered by either on-site generator (120v AC), or site-supplied power. A laptop computer allocated to the logging unit is used to monitor encoder depth positions, control the winch motor, and record detector responses.

RPP-RPT-56849, Rev. 0

3.1 Gross Gamma Calibration and Surveys

The gross gamma is obtained using the efficiency superior BGO instrument response. The settings of the detector components are fixed (i.e. set up during assembly, prior to calibration) and are not adjustable by the field-logging engineer. The detector gain and lower threshold are set to record gamma ray activity with energies between 20 and 3000 keV. By comparison, the highest gamma ray from naturally occurring radionuclides is from thorium-232 and occurs at 2614 keV. A natural thorite mineral containing ^{232}Th and ^{238}U is used as a field verifier at the beginning and ending of each day's logging activities to check detector resolution (integrity) and energy calibration (amplifier gain).

The BGO detector was calibrated in gross gamma borehole calibration models located at the U.S. DOE Hanford site near Richland, Washington. Calibration data were collected in the two most appropriate (lowest concentration) gross gamma calibration zones (SBA and SBU). The detector was covered with a 4-ft long section of the direct push casing (0.37-inch thick). The calibration data are summarized in Table 1. The calibration units are pCi/g of equivalent Radium-226 (eRa-226). See Appendix B for the calibration certificate.

Table 1. Gross Gamma Calibration Data

Calibration Model	Concentration eRa-226 (pCi/g)	Dead-Time Corrected Gross Gamma Count-Rate ¹ (cps)
SBA	61.2	2517±2
SBU	186	7347±3.5

Count rates are mean of 50 sample measurements at 10-sec each.

¹ BGO Detector system dead time is 7.2 microsec

The BGO/LaBr gamma surveys were logged at 0.5 ft depth increments and 100 seconds per station. A spectrum of 1024 channels was collected each 0.5 feet from the bottom of the probehole to the surface. The spectra were recorded in comma-delimited format with all spectra per file. Detector count rates were dead-time corrected and the gamma survey data were processed as gross gamma response to determine the concentration of equivalent Radium-226 (eRa-226) in pCi/g.

The dead time correction is a nonparalyzable relationship (Knoll, 1979) and described by the following equation:

$$C_t = \frac{C_{obs}}{1 - \varepsilon \cdot C_{obs}}$$

Where:

- C_t = the true or dead time corrected count rate in c/s
 C_{obs} = the observed count rate in c/s
 ε = the dead time factor of 7.2 μs .

RPP-RPT-56849, Rev. 0

3.2 Spectral Gamma Calibrations and Surveys

Calibration of the BGO logging system was performed in the four spectral gamma borehole calibration models located at the U.S. DOE Hanford Site near Richland, Washington and according to Hanford Site procedures for scintillation type spectral gamma ray borehole detectors (Randall & Stromswold, 1995). The four calibration models contain elevated concentrations of the naturally occurring radionuclides (potassium, uranium or radium in secular equilibrium with uranium, and thorium, aka KUT). The radionuclide concentrations are traceable to NIST standards (Steele & George, 1986). Table 2 lists the radionuclide concentration in each of the gamma calibration models. The uncertainty is quoted at the 2-sigma (95%) confidence level.

Table 2. Hanford calibration model values for KUT

Model	⁴⁰ K Concentration (pCi/g)	²²⁶ Ra Concentration (pCi/g)	²³² Th Concentration (pCi/g)
SBK	53.50 ± 1.67	1.16 ± 0.11	0.11 ± 0.02
SBU	10.72 ± 0.84	190.52 ± 5.81	0.66 ± 0.06
SBT	10.63 ± 1.34	10.02 ± 0.48	58.11 ± 1.44
SBM	41.78 ± 1.84	125.79 ± 4.00	39.12 ± 1.07

The calibration was performed with a section of the direct push casing (4-ft long) 0.37-in. thick (2.5-in. OD) installed over the detector (4-in. long). Performing the calibration inside the casing is more rigorous than performing the calibration in an open hole and applying a correction factor to account for the presence of the direct push casing.

During logging, the gamma peak at 1461 keV from potassium (K-40) is almost always present as the dominant peak in each spectra. The second best peak is the 2614 keV peak from ²³²Th. Both of these peaks are used to monitor for spectra gain changes. During data processing the spectra gain is adjusted to track the reference gamma peaks.

Borehole survey spectra (100 seconds each) were measured each 0.5 feet between the selected depth intervals in move-stop-acquire logging mode. The results are presented on the plot for each of the corresponding probeholes.

3.3 Spectral Photo Peak Calibrations and Surveys

The LaBr spectral data are processed differently than the BGO data, and thus the LaBr calibration is different. The LaBr calibration is performed in the same manner that the HPGe log data are calibrated (Randall, 1994). The basic concept involves the non-linear least square fitting of a linear background plus a Gaussian photo peak over a small region of the spectra containing the target gamma ray. The discussion in this report will cover the target gamma ray of ¹³⁷Cs (661 keV), but the same technique can be applied to any other gamma ray.

RPP-RPT-56849, Rev. 0

The SBU calibration model was used to measure the LaBr detector efficiency for the 609 keV peak from a daughter product of ^{238}U . The gamma ray detection efficiency of LaBr is a function of energy, thus a method of correcting the measured efficiency at 609 to the efficiency at 661 keV was developed. MCNP (RSICC) code for making Monte Carlo gamma transport calculations was used to compute the ratio of detector efficiencies between 609 and 661 keV. This ratio was then applied to the measure efficiency at 609 keV to obtain the ^{137}Cs gamma ray efficiency. The tool geometry of the modeling was the same used in the SBU calibration, and the source was set to both a 609 and 661 keV distributed throughout an SBU matrix.

The dead time for the LaBr instrument was measured to be 1.06 μs . The measured detector efficiency for the 661 keV is 0.588 (c/s)/pCi/g (Appendix B contains the calibration certificate). The measured FWHM% for the ^{137}Cs photo peak is 4.17% at 661 keV.

The log data processing for ^{137}Cs was performed using a MathCad® file. The steps to process the data are the following:

1. The energy calibration is established.
2. Based upon the 661 keV energy, the predicted peak channel is computed from the energy calibration.
3. A MathCad file is used to fit a linear background plus a Gaussian (with the energy computed centroid, and established peak width) to each spectral record.
4. Within the same MathCad file, the photo peak count rate is computed, the dead time corrected, the calibration coefficients are applied, and the ^{137}Cs concentrations and depths are output to a comma delimited file.
5. Survey plots are made with only those computed ^{137}Cs that are above minimum detect levels, which is conservatively set at 0.7 pCi/g, based upon the statistical merits of the fitting.

4 Conclusion

Scintillation gross, spectral gamma, and moisture survey logs were collected in two probeholes installed in the 241-SX Tank Farm. All probeholes were pushed to their target depth, one planned push was aborted because of refusal to advance; thus leaving only two pushed boreholes to log. Both probeholes were pushed to approximately 150 feet in depth.

No ^{137}Cs , above the minimum detect level, was identified in the two probeholes logged. Thus the ^{137}Cs plot tracks are blank; refer to the plots in Appendix A.

Certificate of Calibration

BGO-1

Feb 4, 2013

Data were taken at the Hanford KUT models on Feb 4, 2013. BGO-1 is the designated Scintillator tool. The SBA model was used for the gross gamma calibration. Fifty spectra were recorded for the model in order to perform statistical analysis. The observed deviations were seen to be near the theoretically predicted variation; refer to the files compressed: Stats.xls for this analysis.

The instrument was covered with 0.37 inch wall-thickness direct push casing.

The coefficient analysis is determined by the algorithm described in the document WHC-SD-EN-TI-293, Rev. 0. The gross gamma calibration for equivalent ^{226}Ra in pCi/g is a regression function and is generally defined by:

$$\text{Ra} = a * \text{GR} + b$$

Where Ra is the Eq. ^{226}Ra in pCi/g, and GR is the observed gross gamma count rate (c/s), dead time corrected. The coefficients of a & b are the fit coefficients. A more physical relationship constrains the intercept (b) to a zero value. This computation yields improved response extrapolated to low concentrations of K, U, and Th (clean zones). The coefficients were determined to be:

$$a = .0243 \quad \text{Eq. } ^{226}\text{Ra pCi/g} / (\text{c/s})$$

$$b \equiv 0$$

at energy threshold of 0keV

$$a = .194 \quad \text{Eq. } ^{226}\text{Ra pCi/g} / (\text{c/s})$$

$$b \equiv 0$$

at energy threshold of 800keV

Certificate of Calibration

BGO-1

Feb 4, 2013

Data were taken at the Hanford KUT models on Feb 4, 2013. BGO-1 is the designated Scintillator tool. Four models were used for Spectral KUT calibration. Fifty spectra were recorded for each model in order to perform statistical analysis. The observed statistical deviations were seen to be within the theoretically predicted variation, refer to the files compressed: Stats.XLS for this analysis. The instrument was covered with 0.37 inch wall thickness direct push casing.

The algorithm described in the document WHC-SD-EN-TI-293, Rev. 0, determines the coefficient analysis. Three energy windows are used for each potassium, uranium and thorium (K U & T), and these are:

K: 1320-1575 keV**U: 1650-2390 keV****T: 2475-2765 keV**

The concentration for each of the three elements is a linear combination of the count rates in the three windows. The resulting coefficients for each of the three elements are:

Concentration-K =	4.077*K	-3.382*U	2.957*T
Concentration-U =	0.0*K	1.351*U	-2.585*T
Concentration-T =	0.0*K	-0.034*U	1.655*T

Where K U & T are the count rates (c/s) in the listed energy windows and the resulting concentration values are in pCi/g.

RPP-RPT-56849, Rev. 0

Certificate of Calibration

LaBr-1

Cs-137 Photo Peak

Sep 13, 2012

Data were taken at the Hanford KUT models on Sep 13, 2012. LaBr-1 is the designated Scintillator tool. The SBA and SBU models were used for the gross gamma calibration. Ten spectra were recorded for each model in order to perform statistical analysis. The observed deviations were seen to be near the theoretically predicted variation, refer to the files compressed: Stats.xls for this analysis.

The instrument was covered with 0.33 inch wall-thickness direct push casing.

The coefficient analysis is determined by the algorithm described in the document WHC-SD-EN-TI-292, Rev. 0. The photo peak stripping method of radionuclide calibration is generally defined by:

$$C = A / (\epsilon * N)$$

Where C is the radionuclide concentration in pCi/g, A is the deadtime corrected photo peak count rate, ϵ is the detector efficiency, and N is the number of gamma rays emitted per decay. The coefficient ϵ is the fit coefficient. The LaBr scintillator has superior energy resolution, but internal to the crystal a small but observable radioactivity that produces a background. This background does not affect the photo peak stripping method. The coefficient was determined to be:

$$\epsilon = .588 \quad (\text{c/s}) / \text{pCi/g}$$

***Certificate of Calibration for
Instrument N-2_097***

Jan 25, 2013

Data were taken in the Moisture models on Jan 25, 2013 for N-2_097 neutron-neutron moisture tool. The neutron source from DOE moisture tool ID of 78-1097 was used with the passive neutron detector probe from PNG.

Six models were used for moisture calibration, 3 for 6" casing and 3 for 8" casing. Repeated spectra were recorded for each model in order to perform statistical analysis. The observed statistical variation agreed with the theoretically predicted variation; refer to the file Stats.xls for this analysis.

The coefficient generation is determined by the algorithm described in the document WHC-SD-EN-TI-306, Rev. 0. The regression function used is a power law form and defined by:

$$V = a \cdot CR^\alpha$$

Where V is the formation moisture content in volume fraction water in vf units. One vf unit is 1% by volume water. The coefficients a and α are fit coefficients, and CR is the deadtime corrected observed total count rate, (c/s).

6" casing
a = .0001671
 α = 2.202

8" casing
a = .00009656
 α = 2.44

The undersigned certifies that the data archived in data file "N-2_097_2013.zip" were collected and evaluated in accordance with procedures WHC-SD-EN-TI-306, "Radionuclide Logging System In Situ Vadose Zone Moisture Measurement Calibration" and that the above stated calibration coefficients are correct and applicable for tool N-2_097, effective Jan 25, 2013.

SX Pore-water Test – Location C8760 Sample Depths
February 12, 2013

Attendees: Melissa Holm, Les Fort, Ann Shrum, Harold Sydnor, Mike Barnes, Kent Reynolds, Cindy Tabor, Joe Caggiano, Susan Eberlein, Dan Parker, Maria Skorska, Mike Truex, Mart Oostrum, and RD Hildebrand

Locations Discussed: C8760

Outcome: All Sample Depths identified below were agreed upon by attendees

Summary Information:

Support Information Provided/Discussed Help Determine Soil Sample Depths:

- Location Map of Current and Prior Direct Push Efforts
- C8759 Draft and Process Gamma and Moisture Plots
- Prior Direct Push - Gamma and Moisture Plots
- Prior Direct Push – Analytical Results
- Information from Well 299-W23-19 (SW of Tank 115)

Log Info:

- Gross Gamma Count (counts/second) – Indicates Geologic Change (In general, the lower the count the coarser the grain and the higher the count the finer the grain)
- Neutron Moisture Count (counts/second) – Moisture Range (Processed Logs 5-40% moisture)

Prior Investigations:

- C7169 approx. 140 ft and C7167 approx. 96ft away from location of interest (locations are approx. 11 ft difference in surface elevation 664-666 ft amsl)
 - C7169/C7170 highest nitrate concentration of 990 µg/g was at 113-115 ft bgs (approx. at 104 ft bgs at C8759)
 - C7167/C7168 highest nitrate concentration of 1,950 µg/g was at 129-131 ft bgs (approx. at 117 ft bgs at C8759)
- 299-W23-19 highest nitrate concentration 24,000 mg/L at 130 ft bgs (approx. 120 ft bgs at C8759)

General Discussion:

- Two Sample Depths of 104 – 106 and 122.5 – 124.5 ft bgs were recommended
 - 104 – 106 ft bgs had an estimated moisture content per volume of 22% (less than what PNNL recommended) – so this sample depth was eliminated as a choice
- A deeper interval of 140 ft bgs was brought up in discussion; however, higher known contamination at the 123 interval seemed more promising – so focus was continued on the 123 ft bgs interval
- In the end, it was determine that the 123 interval was most promising and that characterizing the area above and below this interval would gain valuable information for test design (Thus, 3 samples back to back: 121 – 127 ft bgs).

Table 1: Sample Depth for C8760

Location Log Hole/Sample Hole	Sample Depth (ft bgs)	Reason
C8759/C8760	121 – 127 (3 consecutive sample intervals)	<ul style="list-style-type: none"> • Cold Creek upper (PPLu) - uniform grain size above and finer grain below a higher moisture interval • 35% moisture (within PNNLs criteria): 122.5 – 122.4 ft bgs • Similar zone to C7168 and 299-W23-19 where higher nitrate and Tc-99 concentrations have occurred

Stratigraphic info

Higher moisture per Processed Log (highest moisture is 40%)

ESTIMATED NUMBER OF SAMPLES	30		

SAMPLING ORGANIZATIONS

LABORATORY/PRICE_CODE/PRIORITY TURNAROUND/REQUIRED TURNAROUND/DATA DELIVERABLE

Primary / 222-S Lab Operations / C03 / 60 Days / 120 Days / Interim Results & Summary

SAF COMMENT

****GENERAL**

The applicable FSAP is RPP-PLAN-54366. (Analytical and Quality Control information is summarized in Tables 3-1, 3-2, and 4-1). There are 3 sampling sites and at each sampling site there will be approximately 2 vertical samples taken.

****FIELD**

Material from the shoe will be put into 500 ml glass jar.
Field personnel will cap liners. When capping is not possible or the liners cannot be removed from the sampler, field personnel shall put material into a 250 ml or 500 ml glass jar.

****LABORATORY**

Bulk Density will be determined for each liner, then the material from the liners and shoe (glass jar assigned to generic testing) shall be composited and analyzed. A Quick Turn sample will be analyzed for nitrate, pH, Tc-99 and conductivity on a 1:1 water digest. The nitrate and Tc-99 results will be reported on an expedited time frame (typically within one week of the last sample receipt batched together; however, upon request, results will be reported within 48 hours). The remainder of the composited material will be used for the rest of the analyses and will be reported with the pH and conductivity results in the final analysis report.

The final data package should be in Format VI with QA verification.

222S will transmit all COCs to IDMS.

SAF REVISION COMMENT

COC COMMENT

After bulk density is determined on the liners, the material from the liners and shoe (500 ml glass jar assigned to generic testing) shall be composited.

SAF COMMENT

****GENERAL**

The applicable FSAP is RPP-PLAN-54366 (refer to Change Notice 1). Analytical Information for Stage III Porewater sampling is provided in Table 3-2 and in Change Notice 1.

****FIELD**

There will be approximately two equipment rinses – one at the beginning and one at the end of the project and there will be one field blank.

****LABORATORY**

222S will transmit all COCs to IDMS.

Technical Memorandum

To: Kent Reynolds, EnergySolutions Government Group

From: Kevin Lindsey, LHg

Date: 05 April 2013

Re: Vadose Zone Falling Head Test Evaluation

The goal of this technical memorandum (tech memo) is to report on GSI's conclusions from the review and evaluation of data collected from five vadose zone falling head tests conducted in a borehole near the SX Tank Farm. These falling head tests were conducted in a small diameter boring installed by EnergySolutions Government Group (EnergySolutions) staff in the vadose zone at a test site near the SX Tank Farm. The purpose of the falling head tests was to collect data describing the effectiveness of well development techniques used in these borings to break down the compacted material that accumulates on the boring walls as drill rods are pushed into the ground using hydraulic/vibratory push techniques. For the purposes of this tech memo this material is referred to as the compaction skin.

This tech memo includes a brief summary of the data GSI worked with, our interpretations of that data, and recommendations for future work. The work reported on herein was done under EnergySolutions Government Group Purchase Order #631861.

Data and Interpretations

The primary data set GSI used for this work consists of pressure data collected by a pressure logging transducer installed in the tested boring during a series of five falling head tests done between 12 March and 20 March 2013. The falling head tests were done, as noted above, to assess the success in breaking down the compaction skin that formed on the borehole wall during installation of the boring. The falling heads tests were done following instructions prepared jointly by GSI and EnergySolutions staff prior to field deployment. Attachment 1 shows the basic configuration of the boring during the tests.

The general timeline for these series of falling head tests, excerpted from EnergySolutions field notes, is summarized below.

1. **Test 1, 12 March 2013.** Using 1 gallon of water the boring was surged and purged for approximately 1 hour and 15 minutes. At the completion of that activity 1 gallon of

RPP-RPT-56849, Rev. 0

water was added to the boring at approximately 1218. At 1415 an additional 2 gallons was added to the boring and the falling head test commenced. This test ended the following morning with most of the water having drained away.

2. *Test 2, 13 March 2013.* After adding water to, and surging and bailing the boring for several hours test 2 commenced at approximately 1415 with the addition of 2 gallons of water. This falling head test ended at 0739 the following morning.
3. *Test 3, 14 March 2013.* After adding water to, and surging and bailing the boring for approximately 1.5 hours test 3 commenced at approximately 1054 with the addition of 2 gallons of water. This falling head test ended at 0707 on 18 March.
4. *Test 4, 18 March 2013.* After adding water to, and surging and bailing the boring for approximately 1.5 hours test 4 commenced at approximately 1054 with the addition of 2 gallons of water. This falling head test ended at 1103 the following morning.
5. *Test 5, 19 March 2013.* After adding water to, and surging and bailing the boring for approximately 0.75 hours test 5 commenced at approximately 1232 with the addition of 2 gallons of water. This falling head test ended the following morning.
6. Water bailed from the boring as the test progressed was observed to be progressively less turbid. Field staff reported that water dialed from the boring during Tests 4 and 5 was significantly less turbid that that bailed during Tests 1 and 2.

During each falling head test a pressure transducer was deployed in the boring to measure head changes in it as the 2 gallon slug of water drained out of the boring. The pressure transducer was programmed by field staff to record data logarithmically. Pressure transducer data was provided to GSI in digital form as a csv file downloaded from the transducer. GSI converted that csv file to an xls file for review and evaluation. Hydrographs of the data from the 5 falling head tests are included with this tech memo as Attachment 2.

Visual examination of Attachment 2 shows that during the first 100 plus seconds of each tests water levels rose. This is interpreted to show the pouring of the 2 gallon test volume into the boring. For that reason this following discussion focuses on the data collected after 100 seconds as that data is interpreted to provide the most information regarding the progress of development and the breaking down of the compaction skin coating the boring wall.

Generally, one sees that in Tests 1 and 2 water levels rose and/or were static between 100 and 500 to 600 seconds into the test. Conversely, in Tests 3, 4, and 5 water levels began to decline between 100 and 200 seconds into each test. Later in the tests both Test 1 and 2 show that the boring took in excess of 60,000 seconds to drain while in Tests 3, 4, and 5 the boring was largely drained by 10,000 to 20,000 seconds into the test.

The decline rates versus time for tests 1 through 4 are plotted on Attachment 3. This plot shows that water level decline rates per unit time were much lower (less than -0.002 feet/sec) and steady in Tests 1 and 2. Conversely, in Tests 3 and 4 the initial decline rates were much higher (up to -0.005 ft/sec) throughout the tests. Based on the visual examination of this data as portrayed on Attachments 2 and 3, development, in the form of surging and purging, is interpreted to have broken down the compaction skin between Tests 2 and 3, allowing the 2 gallon slug of water introduced into the boring to drain significantly faster. The similarities in the hydrographs for Test 3, 4, and 5 shown in Attachment 2 suggests that the development

RPP-RPT-56849, Rev. 0

work conducted between Tests 4 and 5 yielded little to no additional improvement in compaction skin breakdown, and that the boring was as developed as this technique could accomplish.

Additional comments and interpretations specific to each falling head test are given below.

Test 1: The hydrograph of Test 1 (Attachment 2) shows increasing water in the boring from the end of pouring in the slug (~100 sec) to approximately 225 seconds. Then the water level in the well begins to fall gradually for the duration of the test. It appears that the slug did not rapidly flush out of the screen but instead seeped out over a long time period. Average rates of change during the first, second, and third log cycles were -0.00069 ft/sec, -0.00096 ft/sec, and -0.00042 ft/sec, respectively (Table 1).

Table 1. Average Falling Head Rate of Change for each Log Cycle.

<i>Test</i>	<i>100-1000 seconds</i>	<i>1000-10000 seconds</i>	<i>10000-60000 seconds</i>
1	-0.00069 ft/sec	-0.00096 ft/sec	-0.00042 ft/sec
2	0.00271 ft/sec	-0.00040 ft/sec	-0.00025 ft/sec
3	-0.00289 ft/sec	-0.00193 ft/sec	Test complete
4	-0.00405 ft/sec	-0.00207ft/sec	Test complete

Using Test 1 data a Darcy's Law permeability of approximately $1.0E-8$ cm² is estimated (Darcy, 1856; Bear, 1972). Using bulk density data provided by EnergySolutions for silty fine sands such as the boring likely penetrates, natural formation permeability estimated using the Kozeny-Carman method is approximately 3.0 to $4.0E-8$ cm² (Carman, 1956; Saar and Manga, 1999). Comparing Test 1 estimated permeability to bulk density estimated permeability suggests that the boring compaction skin has 3 to 4 times less permeability than natural formation materials.

Test 2: The hydrograph of Test 2 (Attachment 2) shows increasing water level in the boring from the end of pouring in the slug (~100 sec) to approximately 530 seconds. Then the water level in the well begins to fall gradually for the duration of the test. It appears that the slug did not rapidly flush out of the screen but instead seeped out over a long time period. The rate of change from 800 to 60,000 seconds in Test 2 is less than the rate of change during the 2,000 to 60,000 second interval in Test 1. Average rates of change during the first, second, and third log cycles were 0.00271 ft/sec, -0.00040 ft/sec, and -0.00025 ft/sec, respectively (Table 1).

Using Test 2 data a Darcy's Law permeability of approximately $1.0E-8$ cm² is estimated (Darcy, 1856; Bear, 1972). Using bulk density data provided by EnergySolutions for silty fine sands such as the boring likely penetrates, natural formation permeability estimated using the Kozeny-Carman method is approximately 3.0 to $4.0E-8$ cm² (Carman, 1956; Saar and Manga, 1999). Comparing Test 2 estimated permeability to bulk density estimated permeability suggests that the boring compaction skin continued to have 3 to 4 times less permeability than natural formation materials at the conclusion of the second test.

RPP-RPT-56849, Rev. 0

Test 3: The hydrograph for Test 3 shows water level immediately decreasing and at a rapid rate from the end of pouring in the slug (~100 sec) to when the water level reaches approximately just above the top of the well screen at 7560 seconds. At this point the falling head test is interpreted to be complete. Rate of water level change in the boring increased rapidly between approximately 100 and 200 seconds. From approximately 400 seconds to 7560 seconds, rate of change decreased at a moderate but relatively constant rate. Average rates of change during the first and second log cycles were -0.00289 ft/sec and -0.00193ft/sec, respectively (Table 1). As noted above, the test was interpreted to be complete when the falling slug reached the bottom of the boring casing at 7560 seconds; this is before the start of the third log cycle.

Using Test 3 data a Darcy's Law permeability of approximately $3.6E-8$ cm² is estimated (Darcy, 1856; Bear, 1972). Using bulk density data provided by EnergySolutions for silty fine sands such as the boring likely penetrates, natural formation permeability estimated using the Kozeny-Carman method is approximately 3.0 to $4.0E-8$ cm² (Carman, 1956; Saar and Manga, 1999). Comparing Test 3 estimated permeability to bulk density estimated permeability suggests that development activities had broken down the compaction skin and that during Test 3 the boring had significant hydrologic connection with formation materials.

Test 4: The results for Test 4 are very similar to Test 3. The hydrograph for Test 4 shows water level immediately decreasing and at a rapid rate from the end of pouring in the slug (~100 sec) to when the water level reaches approximately just above the top of the well screen at 6720 seconds. At 6720 seconds Test 4 is interpreted to be complete. Rate of water level change over time in the boring increased rapidly between 100 and 150 seconds at which point it decreased less rapidly to about 350 seconds. From about 350 seconds to about 6720 seconds, rate of change decreased at a moderate but relatively constant rate. Average rates of change during the first and second log cycles were -0.00405 ft/sec and -0.00207ft/sec, respectively (Table 1). As noted above, the test was interpreted to be complete when the falling slug reached the bottom of the boring casing at 6720 seconds; this is before the start of the third log cycle.

Using Test 4 data a Darcy's Law permeability of approximately $9.8E-8$ cm² is estimated (Darcy, 1856; Bear, 1972). Using bulk density data provided by EnergySolutions for silty fine sands such as the boring likely penetrates, natural formation permeability estimated using the Kozeny-Carman method is approximately 3.0 to $4.0E-8$ cm² (Carman, 1956; Saar and Manga, 1999). Comparing Test 4 estimated permeability to bulk density estimated permeability shows that the formation material in the vicinity of the boring may have a relatively higher than generally estimated. Given that, development activities are interpreted to have broken down the compaction skin and that during Test 4 the boring had significant hydrologic connection with formation materials.

Test 5: The falling head data collected for Test 5 is very similar to that collected for Test 3 and 4 (Attachment 2). Given that, Test 5 is interpreted to show that further development was not necessary and no additional evaluation was done.

Conclusions and Recommendations

Conclusions: Based on the data collected during development and falling head tests conducted by EnergySolutions between 12 March and 20 March 2013, the methodology employed is interpreted to have successfully broken down the compaction skin generated during borehole advance. This data is interpreted to show that following several attempts at development using a surge and purge technique the compaction skin broke down, and with purging this material

RPP-RPT-56849, Rev. 0

was removed from the boring. The falling head rates and permeability estimates seen for Test 3 and 4 versus Test 1 and 2 are interpreted to show successful development.

Based on the data evaluated for this tech memo we conclude that falling head data collected during the first half hour to 1.5 hours of a test can be used to show successful development, as follows:

- In Tests 1 and 2 the first 1000 to 5000 seconds of the tests showed rising, followed by relatively static, to finally slowly decreasing water levels (Attachment 4). This is interpreted to reflect slow drainage of the boring through a relatively undisturbed (undeveloped) compaction skin.
- In Tests 3, 4, and 5 this feature is not seen.
- Instead, in these tests water level immediately begins falling within 100 seconds of it reaching its highest level. In addition, the boring is almost completely drained between 6500 to 7500 seconds (108 to 125 minutes, 2 hours or less) of the start of the test. This is much faster than was seen during Test 1 and 2 where draining was still occurring 50,000 to 60,000 seconds (833 to 1000 minutes, up to 16 hours) following the start of the test.
- We conclude that once development succeeds in breaking down the compaction skin falling head tests will show a change from the trend seen in Test 1 and 2, where water level is relatively static before it begins to fall) to that seen in Tests 3, 4, and 5 where water level begins falling from essentially the beginning of the test.

Recommendations: For future well development activities where conditions similar to those tested between 12 March and 20 March are encountered, and based on the data evaluated herein, GSI recommends the following basic method:

1. Once the borehole is ready for development, add a 2 gallon slug of water to it.
2. Leave this slug of water in the borehole for at least 12 hours. The purpose of this is to have water permeate the compaction skin to begin softening and degrading it preparatory to subsequent surge and purge development.
3. At this point begin development activities using 3 to 4 surge and purge events similar to those used in this effort. Each surge and purge would generally include:
 - a. 30 minutes of surging the 2 gallons of water in the boring.
 - b. Purging that water from the boring.
 - c. Repeating until such time as the purge water is visibly less turbid as compared to the initial purge.
4. When the purge water is visibly less turbid conduct a falling head test.
 - a. In this test one is looking to see if the slug of water stabilizes such as it did in Tests 1 and 2 or quickly begins to fall such as it did in Tests 3, 4, and 5.
5. If the slug shows the slow rise, stabilization, and slow fall seen in the first 30 minutes of Tests 1 and 2 development of the compaction skin is interpreted to be incomplete bullets 3 and 4 above should be repeated.

RPP-RPT-56849, Rev. 0

6. If the slug shows the rapid fall seen in the first 30 minutes of Tests 3, 4, and 5 development is interpreted to be having an effect on the compaction skin. In such a case the final recommended steps are to:
 - a. Purge the well of the slug.
 - b. Add a new clean slug.
 - c. Conduct one 30 minute surge operation followed by purging.
 - d. Add a new 2 gallon slug and conduct another falling head test.
 - e. If the slug is seen to be falling at rates similar to the previous falling head test development can be interpreted to be complete.
 - f. If the slug is seen to be falling at a higher rate, then repeat bullets 6a through 6f.

TIME	WORK SUMMARY			
0530 0600	Safety meeting at office. Topic: Nitrogen Safety.			
0540	Head to SX			
0615	AT SX waiting on RCT's			
0715	RCT's on site, go pull rods and set well is the plan.			
0730	begin well installation. Pull rods back 4' to knock off tip. (Decided to start on C8824)			
0830	Trip out, trip inner rods in with rivet shearing tool and remove.			
0930	inner rods out, pull 2 5/8" to 133 and add bentonite.			
1000	Bentonite is at 133.94, Take lunch			
1030	AT site, waiting for RCT's			
1100	RCT on site. Called Kent about cementing. a decision was made to get everything ready and cement in the morning. Due to SD - so work rest			
1145	Rest (to hot)			
1215	Finish getting ready to do cement.			
1300	Everything is ready to start cementing in the morning go find Steve and explain the plan for tomorrow.			
1330	Head to office			
1400	AT office do paper work			
1430	End shift

TIME	WORK SUMMARY			
0700	Safety meeting at ES office, Topic: Protecting Occupants			
0800	Aced in at 2704 HV			
0835	Pre job. Generators, raise, rad. handtools were main topics.			
0909	Pre job complete. Waiting on electricians.			
0925	CEES on site setting up trailer + equipment.			
1018	Filled mock sump and started bladder pump.			
1033	Filled sampler through sample port.			
1048	Tagged C8823 and determined location of placement of pump and transducer. Placement of transducer was approximately 3 ft. above the pump screen. Placement was determined by CEES representative (Colin Henderson)			
1200	Lunch.			
1312	Delivered and relinquished samples to Todd Steele at 222-S.			
1420	Returned to E.S. for paperwork.			
	NOTE: It's been determined that logging the sample event in a logbook is not necessary. The equipment blank was taken using 222-S lab furnished PE water, placing it in a mock sump (PVC) and pumping it through the tubing prior to the sample port. The same bladder pump was then installed in C8823, 1 inch off the bottom. Sample # B2T085, Co C # V13-006-003, Cooler # TFVS-09-007

Geophysical Logging in the 241-SX Tank Farm, July 2013

1 Introduction

EnergySolutions (ES) and Three Rivers Scientific provided small diameter (slim hole) logging in support of field activities at the 241-SX Tank Farm. Logging surveys were conducted with three detectors: BGO and LaBr (both scintillation tools) and a neutron-neutron moisture tool. The surveys were used for correlation with logs from the SX-boreholes logged earlier in the year (C8759, C8761). This report includes the results of these surveys for the four probe holes installed at the investigation site (see Appendix A).

The BGO and LaBr instruments were run in combination during the logging run, and spectral data were recorded for both. The energy resolution of the LaBr is superior to the BGO, but the BGO efficiency for KUT naturals is superior to the LaBr. Thus the data from the BGO were used to measure gross gamma and concentrations of KUT, and the LaBr data were used to identify and measure the concentrations of selected radionuclides. The targeted radionuclide for this project was ^{137}Cs .

Both of the gamma tools were calibrated for the probe hole conditions present at the investigation site. The moisture tool was calibrated to both 6 and 8 inch-cased calibration standards. A casing thickness correction was applied to the extrapolated casing diameter calibrations for the moisture response.

2 Survey Results

Log surveys were recorded from the bottom of the probe hole (maximum survey depth) to ninety feet below ground surface (bgs). Zero depth reference is at ground surface. A daily repeat measurement was acquired to verify instrument repeatability. The main log and repeat intervals are presented on the same plot. The computed results of the main and repeat intervals were reviewed and the results agree within the uncertainty of the measurement counting statistics.

The survey results for each probe hole are presented as a depth versus concentration plot in Appendix A.

3 Geophysical Logging System

The logging system is a portable unit powered by either on-site generator (120v AC), or site-supplied power. A laptop computer allocated to the logging unit is used to monitor encoder depth positions, control the winch motor, and record detector responses.

RPP-RPT-56849, Rev. 0

3.1 Gross Gamma Calibration and Surveys

The gross gamma was obtained using the efficiency superior BGO instrument response. The settings of the detector components are fixed (i.e. set up during assembly, prior to calibration) and are not adjustable by the field-logging engineer. The detector gain and lower threshold are set to record gamma ray activity with energies between 20 and 3000 keV. By comparison, the highest gamma ray from naturally occurring radionuclides is from thorium-232 and occurs at 2614 keV. A supplied ^{60}Co source was used as a field verifier at the beginning and ending of each day's logging activities to check detector resolution (integrity) and energy calibration (amplifier gain).

The BGO detector was calibrated in gross gamma borehole calibration models located at the U.S. DOE Hanford site near Richland, Washington. Calibration data were collected in the two most appropriate (lowest concentration) gross gamma calibration zones (SBA and SBU). Calibration was performed with a section of the direct push casing (4-ft long) 0.37-in. thick (2.5-in. OD) installed over the detector (4-in. long). The calibration data are summarized in Table 1. The calibration units are pCi/g of equivalent Radium-226 (eRa-226). See Appendix B for the calibration certificate.

Table 1. Gross Gamma Calibration Data

Calibration Model	Concentration eRa-226 (pCi/g)	Dead-Time Corrected Gross Gamma Count-Rate ^{1,2} (cps)
SBA	61.2	2517±2
SBU	186	7347±3.5

1-Count rates are mean of 50 sample measurements at 10-sec each.
2-BGO Detector system dead time is 7.2 microsec

The BGO/LaBr gamma surveys were logged at 0.5 ft depth increments and 100 sec per station.. A spectrum of 1024 channels was collected each 0.5 feet from the bottom of the probe-hole to the targeted 90ft depth. The spectra were recorded in comma-delimited format with all spectra per file. Detector count rates were dead-time corrected and the gamma survey data were processed as gross gamma response to determine the concentration of equivalent Radium-226 (eRa-226) in pCi/g.

The dead time correction is a nonparalyzable relationship (Knoll, 1979) and described by the following equation:

$$C_t = \frac{C_{obs}}{1 - \varepsilon \cdot C_{obs}}$$

Where:

- C_t = the true or dead time corrected count rate in c/s
- C_{obs} = the observed count rate in c/s
- ε = the dead time factor of 7.2 μs .

RPP-RPT-56849, Rev. 0

3.2 Spectral Gamma Calibrations and Surveys

Calibration of the BGO logging system was performed in the four spectral gamma borehole calibration models located at the U.S. DOE Hanford Site near Richland, Washington and according to Hanford Site procedures for scintillation type spectral gamma ray borehole detectors (Randall & Stromswold, 1995). The four calibration models contain elevated concentrations of the naturally occurring radionuclides (potassium, uranium or radium in secular equilibrium with uranium, and thorium (i.e., KUT). The radionuclide concentrations are traceable to NIST standards, (Steele & George, 1986). Table 2 lists the radionuclide concentration in each of the gamma calibration models. The uncertainty is quoted at the 2-sigma (95 %) confidence level.

Table 2. Hanford calibration model values for KUT

Model	⁴⁰ K Concentration (pCi/g)	²²⁶ Ra Concentration (pCi/g)	²³² Th Concentration (pCi/g)
SBK	53.50 ± 1.67	1.16 ± 0.11	0.11 ± 0.02
SBU	10.72 ± 0.84	190.52 ± 5.81	0.66 ± 0.06
SBT	10.63 ± 1.34	10.02 ± 0.48	58.11 ± 1.44
SBM	41.78 ± 1.84	125.79 ± 4.00	39.12 ± 1.07

Calibration was performed with a section of the direct push casing (4-ft long) 0.37-in. thick (2.5-in. OD) installed over the detector (4-in. long). Performing the calibration with the casing is more rigorous than calibration in an open hole and applying correction to account for the presence of the direct push casing.

During logging the gamma peak at 1461 keV from potassium (K-40) is almost always present as the dominant peak in each spectra. The second best peak is the 2614 keV peak from ²³²Th. Both of these peaks are used to monitor for spectra gain changes. During data processing the spectra gain is adjusted to track the reference gamma peaks.

Borehole survey spectra (100 seconds each) were measured each 0.5 feet between the selected depth intervals in move-stop-acquire logging mode. The results are presented on the plot for each of the corresponding probe holes.

3.3 Spectral Photo Peak Calibrations and Surveys

The LaBr spectral data are processed differently than the BGO data, and thus the LaBr calibration is different. The LaBr calibration and log data processing is performed in the same manner that the High Purity Germanium (HPGe) log data are analyzed (Randall 1994). The basic concept involves the non-linear least square fitting of a linear background plus a Gaussian photo

RPP-RPT-56849, Rev. 0

peak over a small region of the spectra containing the target gamma ray. The discussion in this report will cover the target gamma ray of ^{137}Cs (661 keV), but the same technique can be applied to any other gamma ray.

The SBU calibration model was used to measure the LaBr detector efficiency for the 609 keV peak from a daughter product of ^{238}U . The gamma ray detection efficiency of LaBr is a function of energy, thus a method of correcting the measured efficiency at 609 to the efficiency at 661 keV was developed. Monte Carlo N-Particle (MCNP) (RSICC) code for making Monte Carlo gamma transport calculations was used to compute the ratio of detector efficiencies between 609 and 661 keV. This ratio is then applied to the measure efficiency at 609 keV to obtain the ^{137}Cs gamma ray efficiency. The tool geometry of the modeling was the same used in the SBU calibration, and the source was set to both a 609 and 661 keV distributed throughout an SBU matrix.

The dead time for the LaBr instrument was measured to be $1.06\mu\text{s}$. The measured detector efficiency for the 661 keV is 0.588 (c/s)/pCi/g (Appendix B contains the calibration certificate). The measured Full Width Half Maximum (FWHM) % for the ^{137}Cs photo peak is 4.17% at 661 keV.

The log data processing for ^{137}Cs is performed using a MathCad file. The steps to process the data are the following:

1. The energy calibration is established.
2. Based upon the 661 keV energy, the predicted peak channel is computed from the energy calibration.
3. A MathCad file is used to fit a linear background plus a Gaussian (with the energy computed centroid, and established peak width) to each spectral record.
4. Within the same MathCad file the photo peak count rate is computed, dead time corrected, the calibration coefficients are applied and the ^{137}Cs concentrations and depths are output to a comma-delimited file.
5. Survey plots are made with only those computed ^{137}Cs that are above minimum detect levels (mdl), which is conservatively set at 0.4 pCi/g , based upon statistical merits of the fitting.

4 Conclusion

Scintillation gross, spectral gamma, and moisture survey logs were collected in 4 probe holes installed in the 241-SX Tank Farm. All probe holes were pushed to their target depth. All probe holes were pushed to approximately 150 feet in depth.

No ^{137}Cs , above mdl, was identified in the 4 probe holes logged. Thus the ^{137}Cs plot tracks are blank; refer to plots in Appendix A.

Gamma Survey Results

Gross gamma, KUT spectral, ^{137}Cs , and moisture responses are shown in the survey plots for the four probe holes installed in the 241-SX Tank Farm. All detector count rates were dead-time corrected and the results were converted using the calibration coefficients. The plots, with header information, follow.

RPP-RPT-56849, Rev. 0

Certificate of Calibration BGO-1

Feb 4, 2013

Data were taken at the Hanford KUT models on Feb 4, 2013. BGO-1 is the designated Scintillator tool. The SBA model was used for the gross gamma calibration. Fifty spectra were recorded for the model in order to perform statistical analysis. The observed deviations were seen to be near the theoretically predicted variation, refer to the files compressed: Stats.xls for this analysis.

The instrument was covered with 0.37 inch wall-thickness probe-tubing.

The coefficient analysis is determined by the algorithm described in the document WHC-SD-EN-TI-293, Rev. 0. The gross gamma calibration for equivalent ^{226}Ra in pCi/g is a regression function and is generally defined by:

$$\text{Ra} = a \cdot \text{GR} + b$$

Where Ra is the Eq. ^{226}Ra in pCi/g, and GR is the observed gross gamma count rate (c/s), dead time corrected. The coefficients of a & b are the fit coefficients. A more physical relationship constrains the intercept (b) to a zero value. This computation yields improved response extrapolated to low concentrations of K, U, and Th (clean zones). The coefficients were determined to be:

$$a = .0243 \quad \text{Eq. } ^{226}\text{Ra pCi/g} / (\text{c/s})$$

$$b \equiv 0$$

at energy threshold of 0keV

$$a = .194 \quad \text{Eq. } ^{226}\text{Ra pCi/g} / (\text{c/s})$$

$$b \equiv 0$$

at energy threshold of 800keV

Certificate of Calibration

BGO-1

Feb 4, 2013

Data were taken at the Hanford KUT models on Feb 4, 2013. BGO-1 is the designated Scintillator tool. Four models were used for Spectral KUT calibration. Fifty spectra were recorded for each model in order to perform statistical analysis. The observed statistical deviations were seen to be within the theoretically predicted variation, refer to the files compressed: Stats.XLS for this analysis. The instrument was covered with 0.37 inch wall thickness probe tubing.

The algorithm described in the document WHC-SD-EN-TI-293, Rev. 0, determines the coefficient analysis. Three energy windows are used for each potassium, uranium and thorium (K U & T), and these are:

K: 1320-1575 keV

U: 1650-2390 keV

T: 2475-2765 keV

The concentration for each of the three elements is a linear combination of the count rates in the three windows. The resulting coefficients for each of the three elements are:

Concentration-K =	4.077*K	-3.382*U	2.957*T
Concentration-U =	0.0*K	1.351*U	-2.585*T
Concentration-T =	0.0*K	-0.034*U	1.655*T

Where K U & T are the count rates (c/s) in the listed energy windows and the resulting concentration values are in pCi/g.

Digital files condensed as Cal_BGO-1_2013-v0.zip. This compressed file contains:

Certificate of Calibration
LaBr-1
Cs-137 Photo Peak
 Sep 13, 2012

Data were taken at the Hanford KUT models on Sep 13, 2012. LaBr-1 is the designated Scintillator tool. The SBA and SBU models were used for the gross gamma calibration. Ten spectra were recorded for each model in order to perform statistical analysis. The observed deviations were seen to be near the theoretically predicted variation, refer to the files compressed: Stats.xls for this analysis.

The instrument was covered with 0.33 inch wall-thickness probe-tubing.

The coefficient analysis is determined by the algorithm described in the document WHC-SD-EN-TI-292, Rev. 0. The photo peak stripping method of radionuclide calibration is generally defined by:

$$C = A / (\epsilon * N)$$

Where C is the radionuclide concentration in pCi/g, A is the deadtime corrected photo peak count rate, ϵ is the detector efficiency, and N is the number of gamma rays emitted per decay. The coefficient ϵ is the fit coefficient. The LaBr scintillator has superior energy resolution, but internal to the crystal a small but observable radioactivity that produces a background. This background does not affect the photo peak stripping method. The coefficient was determined to be:

$$\epsilon = .588 \quad (\text{c/s}) / \text{pCi/g}$$

***Certificate of Calibration for
Instrument N-2_097***

Jan 25, 2013

Data were taken in the Moisture models on Jan 25, 2013 for N-2_097 neutron-neutron moisture tool. The neutron source from DOE moisture tool ID of 78-1097 was used with the passive neutron detector probe from PNG.

Six models were used for moisture calibration, 3 for 6" casing and 3 for 8" casing. Repeated spectra were recorded for each model in order to perform statistical analysis. The observed statistical variation agreed with the theoretically predicted variation; refer to the file Stats.xls for this analysis.

The coefficient generation is determined by the algorithm described in the document WHC-SD-EN-TI-306, Rev. 0. The regression function used is a power law form and defined by:

$$V = a \cdot CR^{\alpha}$$

Where V is the formation moisture content in volume fraction water in vf units. One vf unit is 1% by volume water. The coefficients a and α are fit coefficients, and CR is the deadtime corrected observed total count rate, (c/s).

6" casing

a = .0001671

α = 2.202

8" casing

a = .00009656

α = 2.44

The undersigned certifies that the data archived in data file "N-2_097_2013.zip" were collected and evaluated in accordance with procedures WHC-SD-EN-TI-306, "Radionuclide Logging System In Situ Vadose Zone Moisture Measurement Calibration" and that the above stated calibration coefficients are correct and applicable for tool N-2_097, effective Jan 25, 2013.

KEVIN A. LINDSEY

Technical Memorandum

To: Kent Reynolds

From: Kevin Lindsey, Ph.D., LHg, Jon Travis

Date: September 30, 2013

Re: Vadose Zone Well Development Falling Head Data Evaluation for Boreholes C8826, C8825, C8824, and C8823

The purpose of this technical memorandum (tech memo) is to report on GSI's review and evaluation of data collected during development of four vadose zone wells, designated C8826, C8825, C8824 and C8823. This review and evaluation was done to assess the effects of well development work on the breakdown of the compaction skin formed during drilling of the boreholes these wells are built in. These wells were installed by EnergySolutions Federal EPC, Inc. (EnergySolutions) staff in the vadose zone at a test site near the 241-SX Tank Farm. Well development work on these wells was done between August 15, 2013 and September 5, 2013.

This tech memo includes a summary of the data GSI worked with, our interpretations of that data, and recommendations for future work based on those interpretations. The work reported on herein was done under EnergySolutions Purchase Order #636148.

Well Characteristics

The wells were installed in boreholes drilled using hydraulic/vibratory push techniques. The wells were built for subsequent use in vadose zone vapor extraction tests. Based on well summaries supplied by EnergySolutions (Attachment 1), basic well specifications are as follows:

- All four wells have a 1 foot, 10 slot screen with a nominal inside diameter of 1.33 inches and outside diameter of 1.66 inches.
- In wells C8826, C8823, C8824, and C8825 the top of the 1-foot screen is 127.35 feet, 128.04 feet, 127.97 feet, and 127.16 feet below ground surface (bgs), respectively. A 4 to 5 foot sump is below the screen.
- In one of these wells, C8825, the 1-foot screen, and the underlying sump, is largely blocked by cement, with the well only open from 127.16 to 127.34 feet bgs.

RPP-RPT-56849, Rev. 0

Following installation of well screens, well development was done to break down the compacted material that accumulates on the boring walls as drill rods are pushed into the ground. For the purposes of this tech memo this material is referred to as the compaction skin.

Methods

The primary data set GSI used to prepare this tech memo consists of falling head data collected by EnergySolutions staff/contractor using a logging pressure transducer installed in each well during specific periods of time during well development. Falling head data was collected in an effort to assess the effectiveness of well development done to breakdown the compaction skin. The falling head tests were designed based on field experiments conducted in the spring of 2013. Field staff was provided with instructions based on the earlier field experiments and prepared jointly by GSI and EnergySolutions staff prior to the August/September field deployment.

Note: The spring 2013 field tests were done on wells with a 2-foot, 20 slot screen, not the 1-foot, 10 slot screen used in the four wells evaluated in this tech memo.

The falling head data evaluated in this tech memo was collected during and following well development generally as follows:

1. Prior to the start of development for a given well a pressure transducer was placed in the well. A two to three gallon slug of clean water was then poured into the well. The pressure transducer recorded the change in head of this slug as it was allowed to drain from the well. This established a pre-development, or baseline, effect of the compaction skin on the well by measuring the falling head.
2. Development then commenced using a surge and purge method where development water introduced into the well was agitated using a surge block.
3. Periodically during surging, development water was pumped or bailed (purged) from the well, the transducer reinstalled, and a two to three gallon slug of clean water was then poured into the well. Purging was intended to remove almost all water, and entrained development fines, from the well. Given that, in several cases during the development of wells C8826 and C8825, some development water was left in the wells prior to the pouring of the 2 to 3 gallon test slug into the well.
4. The pressure transducer recorded the change in head of this slug as it was allowed to drain from the well. This falling head data was then compared to the baseline falling head data to assess the potential impact of development on the breakdown of the compaction skin.
 - a. The pressure transducer was programmed by field staff to record data logarithmically.
 - b. Pressure transducer data was provided to GSI in digital form.

GSI prepared semi-log plots of the falling head data. For each well two semi-log plots were prepared, one where the initial head was normalized to common datum, and one where it was not. The hydrographs are shown in Attachments 2, 3, 4, and 5, and discussed further in the Data and Interpretations section. Comparison between baseline and subsequent falling head tests in each well are based predominantly on visual examination of the data, focusing on the period of time between the end of poring of the test slug into the well (generally between 80

RPP-RPT-56849, Rev. 0

and 100 seconds into the test) and 1,000 seconds. This time period was judged to be adequate for assessing the changes in falling head induced by development because: (1) the falling head slug was completely poured into the well within 100 seconds of the start of the test and (2) previous experience which suggested that 1,000 seconds generally was sufficient to determine if the previous round of development had an effect on the development skin.

Data and Interpretations

Introduction of Test Slug, All Wells

Visual examination of falling head hydrographs for all four wells (see Attachments 2, 3, 4, and 5) show that during the first 80 to 100 seconds of each test water levels rose. This is interpreted to show the pouring of the 2 to 3 gallon test volume into the boring. Loading (poring) of the test slug into the well is reflected in the erratically rising water levels commonly seen between 10 and 80 to 100 seconds on all hydrographs. Given that, the falling head portion of each test is taken as starting between approximately 80 to 100 seconds. The following discussion focuses on the data collected after 80 seconds as that data is interpreted to reflect only draining (the falling head) of the well, and hence providing the information needed to assess the progress of development and breakdown of the compaction skin coating the boring wall.

Well C8826, Falling Head

Development of borehole C8826 started 15 August and ended 28 August 2013. Nine rounds of surging and purging, each followed by a falling head test were completed following the first baseline test. Normalized and unnormalized hydrographs for these falling head tests are found in Attachment 2. Observations from these hydrographs show the following:

- Test 1 showed a relatively constant baseline pre-development falling head drop of approximately 23 feet between 100 and 1,000 seconds.
- The next three tests, test 2, 3, and 4, showed similar decline patterns, if at somewhat reduced rates.
 - This suggests that development had not yet led to the break-up of the compaction skin.
- Falling head tests 5, 7, 8, 9, 10, and 11 show a change in character relative to the prior tests. These later tests show very rapid early declines followed at approximately at the 200 second mark by a sharp reduction in fall rate. Test 6 was not completed due to an equipment malfunction.
 - These falling head patterns are interpreted to reflect initial success in breaking up the compaction skin, followed by replugging of either the borehole wall or the well screen.
 - Possible causes of replugging could be tied to insufficient purging of the well, and consequent removal of development generated fines, prior to the start of the falling head measurements. High pre-falling head test water levels in the well, commonly exceeding 20 feet for many of the slugs, suggest incomplete purging was common during work on this well.
 - Flattening of the decline curve could also be related to loss of driving head as the initial slug declines. We do not currently favor this interpretation as many of

RPP-RPT-56849, Rev. 0

these curves begin to again steepen, suggesting increased drainage rates, as time progresses; suggesting factors other than head are influencing the observed declines.

Well C8825, Falling Head

Development of borehole C8825 started 16 August and ended 29 August 2013. Three rounds of surging and purging, each followed by a falling head test were completed following the baseline test. Normalized and unnormalized hydrographs for these falling head tests are found in Attachment 3. Observations from these hydrographs show the following:

- Test 1 showed a relatively constant baseline pre-development falling head drop of approximately 25 feet between 100 and 1,000 seconds. This rate is similar to what is seen in the baseline for well C8826.
- Tests 2, 3, and 4 on the other hand show a significant reduction in falling head rate. This is interpreted to reflect plugging of the well during development.
- Plugging could be related to the fact that over 90 percent of the screened was later determined by EnergySolutions staff to be blocked by cement. In such a condition, development surging will have had little influence on the compaction skin as it would have limited hydraulic connection with the slug placed in the well for development.

Well C8824, Falling Head

Testing at borehole C8824 started and ended 4 September 2013. Three rounds of surging and purging, each followed by a falling head test were completed following the first baseline test. Normalized and unnormalized hydrographs for these falling head tests are found in Attachment 4. Observations from these hydrographs show the following:

- Test 1 baseline falling head displayed a step-like feature, initially displaying a rapid decline followed by a decrease in decline rate. This is similar to what is seen in later tests in well C8826.
- The step-like decline seen in the baseline falling head is not displayed in the data collected for Tests 2, 3, and 4, data collected after the start of development. These tests suggest that falling head rates were less after development, versus before development. In fact, these tests show a relatively stable water level in the interval between 100 and 1,000 seconds, suggesting little drainage is occurring. This suggests the well was not developed by surge and purge.
- A possible explanation for this may be related to well construction. The small slot size in this well (10 slot) may have influenced development by dissipating development energy. Dissipation of development energy may not result in breakdown of the compaction skin.
- The well may also have plugged during development. A small slot size screen could have been plugged by development generated particulates, blocking the entry of development generated fines into the screen so they could be removed during purging.

RPP-RPT-56849, Rev. 0

Well C8823, Falling Head

Testing at borehole C8823 started 29 August and ended 3 September 2013. Three rounds of surging and purging, each followed by a falling head test were completed following the first baseline test. Normalized and unnormalized hydrographs for these falling head tests are found in Attachment 5. Observations from these hydrographs show the following:

- Like the baseline test in well C8824, the Test 1 baseline falling head in well C8823 displays a step-like feature, initially displaying a rapid decline followed by a decrease in decline rate.
- The step-like decline seen in the baseline falling head is not displayed in the data collected for Tests 2, 3, and 4, data collected after the start of development. In fact, these tests show a relatively stable water level in the interval between 100 and 1,000 seconds, suggesting little drainage is occurring. This suggests the well was not developed by surge and purge.
- A possible explanation for this may be related to well construction. The small slot size in this well (10 slot) may have influenced development by dissipating development energy. Dissipation of development energy may not result in breakdown of the compaction skin.
- The well may also have plugged during development. A small slot size screen could have been plugged by development generated particulates, blocking the entry of development generated fines into the screen so they could be removed during purging.

Conclusions

Based on the data collected during development and falling head tests conducted on wells C8826, C8825, C8824, and C8823 break-down of the compaction skin is interpreted to have been incomplete for several reasons. These are interpreted to include any or all of the following reasons:

1. With incomplete development purging, development produced fines may not be removed from the well. These fines may then plug the screen and/or the borehole wall. This may have occurred in well C8826.
2. The small slot size (10 slot) used in these wells may have hindered development by preventing the movement of development produced fines into the well for removal by purging. Falling head patterns seen in wells C8826 and C8824 (initial rapid fall followed by a quick decrease in decline rate) show trends that suggest replugging of the screen and/or borehole wall during each test.
3. The small slot size in these wells may also have hindered development by dissipating development energy to the point that it had little influence on the compaction skin. Falling head patterns in well C8823, C8824, and C8826 (which commonly show no significant difference between successive development/purge events) show trends that are interpreted to show little or no effect on the development skin by well development.
4. In well C8825 physical plugging of the well screen by cement was a problem.

To conclude, we suspect that the change in well specifications between the spring tests and the August/September deployment compromised the development technique developed and field

RPP-RPT-56849, Rev. 0

tested in the spring for larger screen openings and screened interval. In addition, periodic failure to completely purge development water, and entrained fines, likely contributed to difficulties encountered in the breakdown of the compaction skin. In future work of this type, especially where these small diameter wells are planned, we recommend that techniques and methods be tested on the planned well configuration, not a different configuration.

Mr. Jeff Ayres
State of Washington
Department Of Ecology
3100 Port of Benton Boulevard
Richland, Washington 99354

Subject: Request for Variance to Washington Administrative Code 173-160-451 for Direct Push Resource Protection Wells

Dear Mr. Ayres,

EnergySolutions Government Group, Inc. (EnergySolutions), under contract to Washington River Protection Solutions (WRPS), will be using direct push technology for conducting vadose characterization and investigation in the vicinity of the 241-SX Tank Farms on the Hanford Site, Washington. These direct pushes are for the purpose of investigating the ability to extract pore water from target zones within the vadose zone for potential extraction of TC99 and reduce the moisture content of vadose sediments under and adjacent to SX Tank Farm. The information acquired from this direct push effort will be used to construct an extraction well and associated monitoring wells.

A Notice of Intent to Construct a Soil Boring or Soil Sampling or Vapor Sampling Well, No: SE47030, was submitted and processed on December 18, 2012 for conducting six direct pushes. The current schedule is to initiate the field activities by January 23, 2013. A total of three locations have been selected. A characterization and investigation push will be made at each location, for a total of six direct pushes. Geophysical logging will be conducted in each of the three investigation (logging) pushes. Soil samples will be collected for analysis at up to two selected horizons within the vadose zone in each of the three characterization pushes. At the completion of the investigation/characterization activities, all six direct push probe holes will be decommissioned in accordance with the Washington Administrative Code (WAC) 173-160 requirements.

The target depth for these direct pushes is approximately 130+ ft bgs (below ground surface). A variance to the WAC 173-160-451 is being requested as these direct pushes will be greater than 30 ft in depth. In addition to the soil sampling and geophysical logging activities, several other actions will be performed within these pushes to gather information pertinent to the design of an extraction well and monitoring field. An approval/concurrence for the conduct of these actions is also requested. The sequence of activities to be conducted in support of this pore water extraction test is described below.

2345 Stevens Drive, Suite 240 • Richland, Washington 99354 • 509.371.8006
Fax: 509.375.9886 / 509.371.1906 / 509.375.9500 • www.energysolutions.com

RPP-RPT-56849, Rev. 0

During decommissioning of the investigation boreholes, up to two zones of interest will be tested in each of three locations through placement of a temporary screen and riser pipe, performance of a "falling head" permeability test, and well development surging.

After placement of the screen, the zone will be instrumented with a piezometer and one gallon of water will be introduced into the riser pipe. The decline of the head elevation will be monitored and recorded. When the decline has reached a steady state, the piezometer will be removed and the well will be surged to breakdown the borehole wall compaction to increase the permeability. After surging, the remaining water and debris (sediments) produced through the screen will be removed with a bailer. The piezometer will be replaced and another falling head test will be conducted. This iterative process will be repeated based on direction from the onsite hydrogeologist. At the conclusion of testing, the screen and riser will be removed and the remainder of the borehole will be decommissioned to meet WAC 173-160 requirements. Two to a maximum of six zones of interest will be tested.

Please provide your concurrence in the space provided below and return a copy for our project files. Please contact me at 375-9587 if you require additional information.

Sincerely,

Martin G. Gardner, Manager
Washington Operations

June 6, 2013

FS-NW-LT-5637

Mr. Jeff Ayres
State of Washington
Department Of Ecology
3100 Port of Benton Boulevard
Richland, Washington 99354

Subject: Request for Variance to WAC 173-160-451 for Direct Push Resource
Protection Wells for SX Tank Farm

Dear Mr. Ayres,

EnergySolutions Government Group, Inc. (EnergySolutions), under contract to Washington River Protection Solutions (WRPS), will be using direct push technology for conducting pore water extraction technology testing in the vicinity of the 241-SX Tank Farms on the Hanford Site, Washington. These direct pushes are for the purpose of demonstrating the ability to extract pore water from target zones within the Vadose zone for potential extraction of TC99 and reduce the moisture content of vadose sediments under and adjacent to SX Tank Farm. The information acquired from these temporary constructions is intended to provide information to evaluate the pore water extraction potential for use as a method to reduce contaminate inventory in sub-surface sediments.

A Notice of Intent to Construct a Soil Boring or Soil Sampling or Vapor Sampling Well, No.: SE48334, has been prepared for conducting four direct pushes. The current schedule is to initiate the field activities by June 10, 2013. A total of four locations have been selected. A single direct push casing will be driven at each of the four locations, for a total of four direct pushes. Geophysical logging will be conducted in each of the pushes. At the completion of the logging activities, temporary screen, packer, and sump assemblies will be placed into each hole and, after well permeability activities, pore water extraction testing will be conducted. At the conclusion of the testing phase the direct push probe holes will be decommissioned in accordance with the Washington Administrative Code (WAC) 173-160 requirements.

The targeted total depth for these direct pushes is approximately 150+ ft bgs (below ground surface). A variance to the WAC 173-160-451 is being requested as these direct pushes will be greater than 30 ft in depth. In addition to the geophysical logging activities, several other actions will be performed within these pushes to:

2345 Stevens Drive, Suite 240 • Richland, Washington 99354 • 509.371.8006
Fax: 509.375.9986 / 509.371.1906 / 509.375.9500 • www.energysolutions.com

RPP-RPT-56849, Rev. 0

FS-NW-LT-5637

- 1) Place temporary screen and packer assemblies in the wells; 2) Through surging and conducting falling head data collection actions, improve and quantify the effective permeability of the screen interval; 3) Conduct a two to three month long pore water extraction testing activity; and 4) Decommission the borings at the conclusion of the extraction testing.

The sump assemblies will be cemented in place, the packers above the screen will be inflated, and the screen /sump will be instrumented with a piezometer. Potable water will be introduced into the well screen and the decline of the head elevation will be monitored and recorded. When the decline has reached a steady state, the piezometer will be removed and the well will be surged to breakdown the borehole wall compaction to increase the permeability. After surging, the remaining water and debris (sediments) produced through the screen will be removed with a bailer. The piezometer will be replaced and another falling head test will be conducted. This iterative process will be repeated based on direction from the onsite hydrogeologist. At the conclusion of the development process, pore water extraction testing will be conducted. At the conclusion of testing, as much of the riser and screen assembly as possible will be removed, the remaining tubing, screen assembly, etc., will be filled with bentonite as the outer casing is extracted in compliance with WAC 173-160 requirements for decommissioning.

Please provide your concurrence in the space provided below and return a copy for our project files.

If you have any questions, or require any additional information, please contact me at (509) 375-9587.

Sincerely,

Martin G. Gardner, Manager
Washington Operations

Comments/Items needing addressed
ERGONOMICS—Crew was observed using various techniques when assembling/disassembling the tremmie pipe to reduce repetitive motion fatigue. The falling head test required the addition set volumes of water at the direction of the contracted consultant. Workers performed the task required without skipping safe work practices that reduce the risk of an injury. No further actions required.

RPP-RPT-56849, Rev. 0

SIGNS and BOUNDARIES—Observers parked next to the other vehicles present and were informed by workers present there was a hardhat requirement inside the work boundary. Observers were unclear about the requirement for hardhats based on the following:

- Postings were observed near the entrance to the work site with signage communicating the requirements for hearing protection and authorized personnel only. These postings were not recognized as a work control boundary, as they were part of an incomplete boundary and did not cross the road to restrict/limit access.
- A complete boundary around the HHU-XL equipment was in place and observers found that it was posted for hearing protection and authorized personnel only. The complete nature of the boundary, along with the initially observed postings indicated the purpose was a work control boundary (*see attached images*). Observers also noted the yellow and magenta rope boundary, indicating a radiological function, but found only two signs designating it as an RBA were posted.
- Project personnel were observed in the same parking area as the observers without hardhats or safety glasses.
- The field work supervisor asked each observer to sign the daily site roster, but provided no further clarification on the definition of the work zone and/or the required PPE for the area the observers were located.

Because of PPE inconsistencies observed, and the absence of a posted barricade to communicate specific PPE requirements, a review of the worksite posting practices is recommended.

SIGNS and BOUNDARIES—Observed the personnel inside the RBA perform self surveys (*see attached images*) and then exit by ducking under the rope. Inquired about exit points after the workers exited the RBA. Workers were unaware of any exit points where the rope could be lowered. Upon further inquiry, one of the project personnel was able to show the other workers the locations of the exit points. The self survey area was moved next to the exit point, no further workers were observed ducking under the boundary.

NOISE—Crew staged the generator away from the work area to decrease noise exposure. Upon inquiry, crew was able to explain reducing occupational noise exposure by PPE was a last line of controls, after taking other steps to reduce exposure—like moving the sound source further away. Observers inquired about the positioning of the work control boundary and the verification of boundary placement with sound surveys. Workers were unsure if the data had been collected, or what the results were if it was collected.

It is recommended that all worksite layouts during direct push tasks be evaluated for noise. It is recommended that sound maps be generated in conjunction with routine sound surveys to ensure the worksite boundaries are properly placed. It is recommended that workers be provided information about their occupational noise exposure and that they participate in discussion of how to reduce their exposure.

ELECTRICAL/VEHICULAR TRAFFIC— When an electrical cord was found that appeared to have been driven over, workers demonstrated that they had unplugged the cord, allowed the vehicle access, and then reconnected the system (*see attached images*). Requested the cord be positioned further away from potential vehicle traffic. Observed a support personnel drive over the cord after it was repositioned (*see attached images*) Observed the repositioning of the contractor's vehicle and instruments prior to conducting the falling head test on the borehole to prevent the potential for a tripping hazard on stretched cables (*see attached images*).

RPP-RPT-56849, Rev. 0

Field Safety and Health Inspection Report

REV 1 2/2/11

It is recommended that electrical safety practices / principles be reviewed with the work crew. Despite best effort to move the cord and prevent it from being driven over...it was. It is recommended that when electrical cords and portable electrical systems are used, the location of the cables and any administrative work practices to be used (such as moving the cord for vehicles) be covered during the daily morning meetings prior to work. It is recommended that power cords be protected by conduit, planks, or risers. Do not allow vehicles to drive over unprotected cords.

HAND/POWER TOOLS—No improper use of hand tools observed; tools were inspected prior to use and put away following use. During the falling head test, workers utilized a chain vice grip to hold the tremmie pipe in place (*see attached image*). No further actions required.

HOUSEKEEPING—(*see attached images*) The site layout was clean, with the minimal amount of tools and items needed inside the RBA. Waste bags were positioned to be easily accessible, and secured to prevent contents from spilling/blowing away. Items were staged within easy reach, tripping hazards minimized. No further actions required.

Comments Required for WRPS-Indicate Purpose of Document:

This report details field activities for using small diameter soil borings for extracting pore water from partially saturated sediments. Stage I included field activities to obtain additional information at prospective sites. Stage II includes collecting soil samples for identifying preferred test location and designing test equipment associated with monitoring systems. Stage III includes procurement and installation of monitoring system in four new soil borings.

  <comments>Approved upon incorporation of comments 1.0 in the
  introduction, that first sentence does not make sense. DOE did not assign
  the RPP to anyone, DOE awarded the tank operations contract to WRPS -
  make that factually accurate. 4.0, p. 27, should be "Decommissioning ...
  WAS conducted" not were p A-5 - change the third sentence of the first
  paragraph to, "The tanks were used for storage of chemical and
  radioactive waste produced ..." CHANGE THIS in appendix B too Again in
  1.2 on page A-5, that first sentence, I don't know that DOE "assigned" the
  RPP - DOE awards contracts for work to be completed. CHANGE in
  appendix b too</comments>
