1.0 INTRODUCTION

In order to resolve the issue regarding the existence or nonexistence of Cr(VI) in the 300-FF-1 and 300-FF-5 operable units, a close look at the sample data from representative wells in and around 300-FF-1 was taken. Samples were taken from 20 wells and a total of 686 samples were taken during the period between June 17, 1985, and December 18, 1991.

2.0 GROUNDWATER DATA

The samples were analyzed using Inductively Coupled Plasma (ICP) Emission Spectrometry. Analysis was done on both filtered and unfiltered samples. There were samples taken early in the sampling period, which were not filtered. It is presumed that this was prior to the realization of the need to do both.

Table 1 shows a breakdown of filtered and unfiltered samples for which Cr analysis was done.

Table 1. 300-FF-5 Groundwater Samples.

9 2 1 2 6 5 1 7 9 9

Appendix A provides a detailed listing of the samples and the results of the analysis. Figure 1 shows the location of the wells sampled in relation to the 300 Area process disposal facilities and the Columbia River.

Table 2 shows a breakdown of the lab results for Cr for the entire sample lot.

Table 2. Levels of Cr Analyzed in 300-FF-5 Groundwater.

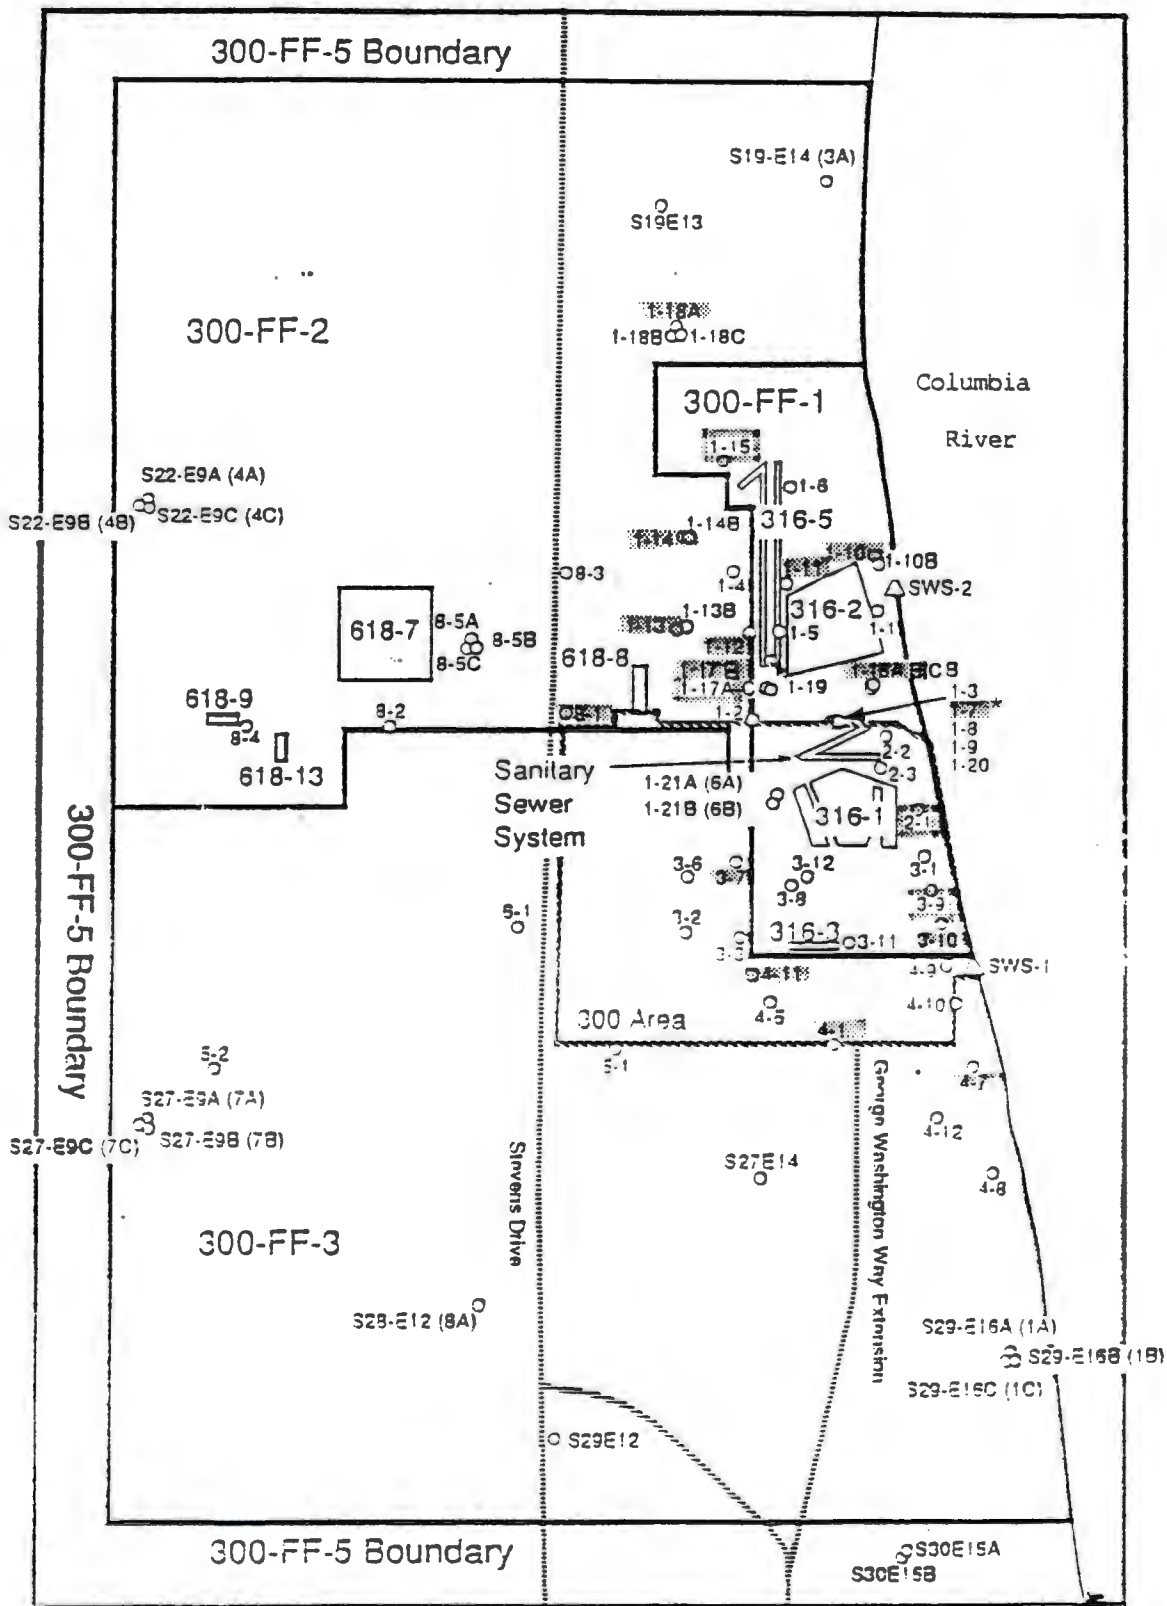

<u>ug/L (ppb)</u>	<u>Unfiltered</u>	<u>Filtered</u>	<u>Total</u>
Cr undetected	351	295	646
Cr < 50 ppb	39	0	39
Cr ≥ 50 ppb	<u>1</u>	<u>0</u>	<u>1</u>
Totals	391	295	686

The location of wells that had detectable Cr can be seen in Figure 1.

Several observations can be made by looking at the breakdown in Table 1. First, only 40 samples out of 391 unfiltered samples (10.2%) had Cr above the method detection limits. By looking at the distribution of the 40 samples (either on Figure 1 or in Appendix A), it is apparent that there is not a concentration of Cr in any particular area or well, nor is there any particular well that shows a consistent presence of Cr in its samples. The 40 samples are divided up among 16 different wells.

Second, only one sample exceeded the safe drinking water limit of 50 ppb. This was a sample taken on December 16, 1991, in well 3-1-7. The level of Cr for this sample was 73 ppb, which, although it exceeds the drinking water limit, does not exceed the freshwater aquatic life standard (100 ppb) set by the U.S. Environmental Protection Agency (EPA) (Quality Criteria For Water, EPA 1976).

Third, the Cr is tied up with the suspended particulates. There were no filtered samples for which Cr was detectible. Of the 40 unfiltered samples in which Cr was detected, 33 have a matching filtered sample. All of the filtered samples came out below detection limits.

- Dark Gray Detectable Cr ≥ 50 ppb

Figure 1. Master Well Map.

## 3.0 SOILS ANALYSIS

Since Cr is tied up with the suspended material, the argument can be made that it is in the form of Cr(III) and not the toxic form Cr(VI). Detection of Cr(VI) in drinking water and groundwater from wastes disposed through recharge basins, diffusion wells, or landfills suggests this form of Cr is not effectively sorbed by the soil (Griffin et al. 1977; Adriano 1986). Since the filtered samples indicate no detectible Cr, it would appear that this Cr is effectively sorbed by the soil.

Adriano (1986) states that soluble Cr may be converted to insoluble forms when added to soils. One process is via reduction of soluble and relatively toxic Cr(VI) to Cr(III). If the Cr is tied up with the suspended particles and can be removed by filtering, it is not soluble and must therefore be in the reduced form of Cr(III). Adriano (1986) goes on to say the results indicate that although Cr(III) could be oxidized to Cr(VI) in soil, this is probably not all that common. On the other hand, when Cr(VI) is added to soil it can be expected to rapidly reduce to Cr(III). Therefore, Cr in most soils probably occurs as Cr(III).

To illustrate the increased potential for Cr(III) versus Cr(VI) to adsorb to particles one can look at the Distribution Coefficients for the two phases. Baes and Sharp (1983) discuss the Distribution Coefficients,  $K_d$ , where  $K_d$  is defined by the following equation:

$$K_d = \frac{C_s}{C_o}$$

where

$C_s$  is the concentration of the solid phase  
 $C_o$  is the concentration in  $H_2O$

Cr(VI) has a Distribution Coefficient between 1.2 and 1,800, whereas Cr(III) is in a much higher range of 470 to 150,000. Clearly, the Cr(VI) is less likely to adhere to particles and, hence more mobile and likely to be transported during infiltration. Conversely, the Cr(III) would be expected to adsorb more readily to particles, be less mobile and more capable of being filtered out of the groundwater.

To further strengthen the argument, Cary et al. (1977) and Adriano (1986) found that Cr(VI) was reduced to Cr(III) at a faster rate in acidic soils versus basic soils. Young and Fruchter (1991) give a list of acids disposed in the 300 Area Process Ponds. It makes sense that the Cr(VI) still remaining in the ponds during periods of acidic discharge would have a greater likelihood to reduce to Cr(III).

9 2 1 2 6 3 5 1 8 0 2

The pH is not the only contributing factor. Reduction of Cr(VI) in soil can be enhanced by the presence of organic material (Cary et al. 1977; Bartlett and Kimble, 1976; James and Bartlett, 1983; Adriano 1986). Young and Fruchter (1991) have indicated that organic chemicals were also discharged to the North and South Ponds, thus increasing the potential for the Cr(VI) to be reduced.

It is feasible that at the time of deposition, the conditions might be such that at least some of the Cr(VI) would not be reduced to Cr(III). As a result of Cr(VI) being soluble and because of the design of the process ponds and the process trenches (i.e., all liquids will infiltrate into the groundwater system and then directly into the river), any Cr(VI) that was not reduced would have gone immediately to the river. Young and Fruchter (1991) reveal that elevated Cr levels were detected in the seep water approximately 7 days after the Cr was discharged to the pond. A logical conclusion from this analysis is that a significant portion of the Cr discharged is no longer onsite.

#### 4.0 CONCLUSION

It is well documented that Cr(VI) was disposed in the 300-FF-1 Process Sewer system during intermittent periods for a great many years. This disposal was discontinued several years ago. The question is whether or not the Cr currently being detected in the 300-FF-1 and 300-FF-5 soil and water samples is Cr(VI) or Cr(III).

The comparison of the unfiltered samples and the filtered samples demonstrates that removal of the suspended material by filtering will remove the Cr to below detection limits. This implies that the Cr is tied up with the suspended material and is no longer insoluble. Due to the high potential for Cr(III) to adsorb to particles and the extreme unlikelihood for soluble Cr(VI) to attach to suspended particles, the Cr assayed in the samples cannot be Cr(VI).

Since Cr(VI) is soluble and hence much more mobile, it is expected that if there were any Cr(VI) that did not reduce to Cr(III) that it would have long since been transported to the river via the groundwater and is no longer onsite.

It should also be noted that the amount of Cr detected in the samples was below the drinking water standard (50 ppb) for 99.7% of the unfiltered samples. Only one sample was over 50 ppb and that sample was still under the freshwater aquatic life standard.

Therefore, it can be concluded that the Cr found in the soils of 300-FF-1 and in the groundwater of 300-FF-5 will cause no significant risk to human health or the environment.
